OF THE

American Medical Association

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES BY

MORRIS FISHBEIN, M.D.

VOLUME 101

JULY—DECEMBER, 1933

AMERICAN MEDICAL ASSOCIATION, CHICAGO, 1933

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1933-1934

HEADQUARTERS OF THE ASSOCIATION, 535 N. DEARBORN ST., CHICAGO

GENERAL OFFICERS

| | |
|---|---------------------|
| PRESIDENT—DEAN LEWIS | Baltimore |
| PRESIDENT-ELECT—WALTER L. BIERRING | Des Moines, Iowa |
| VICE PRESIDENT—JOHN H. MUSSER | New Orleans |
| SECRETARY AND GENERAL MANAGER—OLIN WEST | Chicago |
| TREASURER—HERMAN L. KRETSCHMER | Chicago |
| SPEAKER, HOUSE OF DELEGATES—F. C. WARNSHUIS | Grand Rapids, Mich. |
| VICE SPEAKER, HOUSE OF DELEGATES—NATHAN B. VAN ETEN | New York |
| EDITOR AND GENERAL MANAGER EMERITUS—GEORGE H. SIMMONS | Chicago |
| EDITOR—MORRIS FISHBEIN | Chicago |
| BUSINESS MANAGER—WILL C. BRAUN | Chicago |

BOARD OF TRUSTEES

| | |
|-----------------------------|-----------------------|
| D. Chester Brown | Danbury, Conn., 1934 |
| Allen H. Bunce | Atlanta, Ga., 1934 |
| Joseph A. Pettit | Portland, Ore., 1935 |
| J. H. J. Upham, Chairman | Columbus, O., 1935 |
| Thomas S. Cullen | Baltimore, 1936 |
| Arthur W. Booth | Elmira, N. Y., 1937 |
| Rock Sleyster | Wauwatosa, Wis., 1937 |
| Austin A. Hayden, Secretary | Chicago, 1938 |
| Charles B. Wright | Minneapolis, 1938 |

JUDICIAL COUNCIL

| | |
|----------------------------------|-------------------------|
| James B. Herrick | Chicago, 1934 |
| G. E. Follansbee, Chairman | Cleveland, 1935 |
| Walter F. Donaldson | Pittsburgh, 1936 |
| Edwin P. Sloan | Bloomington, Ill., 1937 |
| John H. O'Shea | Spokane, Wash., 1938 |
| Olin West, Secretary, ex officio | Chicago |

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

| | |
|-------------------------|----------------------------------|
| Emmett P. North | St. Louis, 1934 |
| Reginald Fitz | Boston, 1935 |
| M. W. Ireland | Washington, D. C., 1936 |
| Charles E. Humiston | Chicago, 1937 |
| Frederic A. Washburn | Boston, 1938 |
| R. L. Wilbur, Chairman | |
| | Stanford University, Calif. 1939 |
| James S. McLester | Birmingham, Ala., 1940 |
| W. D. Cutter, Secretary | Chicago |

COUNCIL ON SCIENTIFIC ASSEMBLY

| | |
|--------------------------|------------------------|
| Irvin Abell | Louisville, Ky., 1934 |
| Frank Smithlies | Chicago, 1935 |
| J. E. Lane* | New Haven, Conn., 1936 |
| Frank H. Lahey, Chairman | Boston, 1937 |
| James E. Paullin | Atlanta, Ga., 1938 |

AND EX OFFICIO

The President-Elect, the Editor and the Secretary of the Association.

* Deceased.

COMMITTEE ON SCIENTIFIC EXHIBIT

| | |
|----------------------------|----------------|
| D. Chester Brown, Chairman | Danbury, Conn. |
| Arthur W. Booth | Elmira, N. Y. |
| Allen H. Bunce | Atlanta, Ga. |
| Thomas G. Hull, Director | Chicago |

ADVISORY COMMITTEE

| | |
|----------------------------|------------------|
| George Blumer | New Haven, Conn. |
| Paul J. Hanzlik | San Francisco |
| Ludwig Hektoen | Chicago |
| Urban Mues | New Orleans |
| Hans Zinsser | Boston |
| Eben J. Carey | Milwaukee |
| Frank H. Lahey, ex officio | Boston |

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)

| | |
|--------------------------------|-------------------------|
| Stanhope Bayne-Jones | Washington, D. C., 1934 |
| C. W. Edmunds | Ann Arbor, Mich., 1934 |
| Eugene F. Du Bois | New York, 1934 |
| Morris Fishbein | Chicago, 1935 |
| G. W. McCoy | Washington, D. C., 1935 |
| E. M. Bailey | New Haven, Conn., 1935 |
| George H. Simmons | Chicago, 1935 |
| L. G. Rowntree | Philadelphia, 1936 |
| Toral Sollmann | Cleveland, 1936 |
| Lafayette B. Mendel | New Haven, Conn., 1936 |
| Reid Hunt, Chairman | Boston, 1937 |
| W. W. Palmer | New York, 1937 |
| Alfred F. Hess* | New York, 1937 |
| R. A. Hatcher | New York, 1938 |
| E. E. Irons | Chicago, 1938 |
| H. N. Cole | Cleveland, 1938 |
| Paul Nicholas Leech, Secretary | Chicago |

COMMITTEE ON FOODS

(Special Committee of Board of Trustees)

| | |
|---------------------------|------------------------|
| E. M. Bailey | New Haven, Conn., 1934 |
| Julius H. Hess | Chicago, 1934 |
| G. F. Powers | New Haven, Conn., 1935 |
| Morris Fishbein, Chairman | Chicago, 1935 |
| L. B. Mendel | New Haven, Conn., 1936 |

| | |
|----------------------------|------------------------|
| R. M. Wilder | Rochester, Minn., 1934 |
| Philip C. Jeans | Iowa City, 1937 |
| Mary Swartz Rose | New York, 1937 |
| James S. McLester | Birmingham, Ala., 1938 |
| E. O. Jordan | Chicago, 1938 |
| Raymond Hertwig, Secretary | Chicago |

COUNCIL ON PHYSICAL THERAPY

(Standing Committee of Board of Trustees)

| | |
|-----------------------------|-------------------------|
| Ralph Pemberton | Philadelphia, 1934 |
| Harry E. Mock, Chairman | Chicago, 1934 |
| George Miller MacKee | New York, 1934 |
| W. E. Garrey | Nashville, Tenn., 1935 |
| W. W. Coblentz | Washington, D. C., 1935 |
| John S. Coulter | Chicago, 1935 |
| Robert B. Osgood | Boston, 1936 |
| Frederick J. Gaenslen | Milwaukee, 1936 |
| Howard T. Karsner | Cleveland, 1936 |
| A. U. Desjardins | Rochester, Minn., 1937 |
| Yandell Henderson | New Haven, Conn., 1937 |
| Olin West, ex officio | Chicago |
| Morris Fishbein, ex officio | Chicago |
| Howard A. Carter, Secretary | Chicago |

BUREAU OF LEGAL MEDICINE AND LEGISLATION

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, C. T. Stone, Galveston, Texas; Vice Chairman, F. W. Kerr, University of California

SURGERY, GENERAL AND ABDOMINAL—Chairman, Harold Brunn, San Francisco; Vice Chairman, Roy D. McClure, Detroit; Secretary, Howard M. Clute, 605 Commonwealth Avenue, Boston.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY—Chairman, Joseph B. De Lee, Chicago; Vice Chairman, Paul Titus, Pittsburgh; Secretary, James R. McCord, 50 Armstrong Street, Atlanta, Ga.

OPHTHALMOLOGY—Chairman, William C. Finoff, Denver; Vice Chairman, Frank E. Burch, St. Paul; Secretary, Parker Heath, 1551 Woodward Avenue, Detroit.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY—Chairman, W. P. Wherry, Omaha; Vice Chairman, Robert F. Ridpath, Philadelphia; Secretary, John J. Shea, 1018 Madison Avenue, Memphis, Tenn.

PEDIATRICS—Chairman, Alfred A. Walker, Birmingham, Ala.; Vice Chairman, C. W. Burhans, Lakewood, Ohio; Secretary, Ralph M. Tyson, 334 South 21st Street, Philadelphia.

PHARMACOLOGY AND THERAPEUTICS—Chairman, John H. Musser, New Orleans; Vice Chairman, C. H. Greene, New York; Secretary, Russell L. Haden, 2050 East 93rd Street, Cleveland.

PATHOLOGY AND PHYSIOLOGY—Chairman, William C. MacCarty, Rochester, Minn.; Vice Chairman, Elias P. Lyon, Minneapolis; Secretary, J. J. Moore, 55 East Washington Street, Chicago.

NERVOUS AND MENTAL DISEASES—Chairman, Henry W. Woltman, Rochester, Minn.; Vice Chairman, Thomas J. Heldt, Detroit; Secretary, Henry R. Viets, 6 Commonwealth Avenue, Boston.

DERMATOLOGY AND SYPHILOLOGY—Chairman, C. Guy Lane, Boston; Vice Chairman, Charles C. Tomlinson, Omaha; Secretary, Harry R. Foerster, 208 East Wisconsin Avenue, Milwaukee.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman, Wilson G. Smilie, Boston; Vice Chairman, John P. Koehler, Milwaukee; Secretary, R. R. Sayers, United States Public Health Service, Washington, D. C.

UROLOGY—Chairman, Harry B. Culver, Chicago; Vice Chairman, W. M. Kearns, Milwaukee; Secretary, J. H. Morrissey, 40 East 61st Street, New York.

ORTHOPEDIC SURGERY—Chairman, J. S. Speed, Memphis, Tenn.; Vice Chairman, R. D. Schrock, Omaha; Secretary, Fremont A. Chandler, 180 North Michigan Avenue, Chicago.

GASTRO-ENTEROLOGY AND PROCTOLOGY—Chairman, A. R. R. Andresen, Brooklyn; Vice Chairman, Walter A. Fansler, Minneapolis; Secretary, H. L. Bockus, 250 South 18th Street, Philadelphia.

RADIOLOGY—Chairman, A. U. Desjardins, Rochester, Minn.; Vice Chairman, Amédée Granger, New Orleans; Secretary, John T. Murphy, 421 Michigan Street, Toledo, Ohio.

MELANOSIS COLI

THE ETIOLOGIC SIGNIFICANCE OF THE ANTHRACENE
LAXATIVES: A REPORT OF FORTY-ONE CASES

H. L. BOCKUS, M.D.

J. H. WILLARD, M.D.

AND

JOSEPH BANK, M.D.

PHILADELPHIA

Although melanotic pigmentation of the colon has been recognized for almost a century, there has been surprisingly little written on this subject from a clinical standpoint. In the course of routine sigmoidoscopic examinations, this striking type of discoloration is not infrequently seen. The color of the mucosa varies from buff to dark brown or black, the deeper shade being broken into small angular, polyhedral designs by fine netlike striae of lighter shade, either yellow or brown. These small fields vary in size between 2 and 10 mm. in diameter. Small pinhead yellow follicles are frequently seen, being more noticeable in the milder cases of melanosis. One of the earliest writers likened the appearance of the mucosa of the bowel to that of a toad's back.¹ Others have compared the appearance to a snake, crocodile or tiger skin.² To us the pigmentation suggests somewhat a cross section of nutmeg.

REVIEW OF THE LITERATURE

According to Stewart and Hickman,³ the first reference to a case of melanosis coli was that of Cruveilhier,⁴ who wrote in about 1830: "M. Andral has found in an individual affected with chronic diarrhea, the inner surface of the large intestine as black as chinese ink, from the ileocecal valve right down to the rectum. The color resided in the internal membrane, which showed no other alterations beyond a remarkable development of its follicles." Virchow apparently first applied the name melanosis coli to this condition in 1858. His specimen, labeled in his own hand, is in the pathologic institute in Berlin. In 1898, Solger⁵ reported the autopsy examinations of seven cases which he termed "colitis pigmentosa," a term since discarded because inflammatory changes have not been demonstrated.

Read before the American Gastro-Enterological Association, Washington, D. C., May 8, 1933.

Because of lack of space, this article is abbreviated here by the omission of the tables. The complete article appears in the authors' reprints.

Pick,⁶ in 1911, collected twelve cases from the literature and added six of his own. He was the first to call attention to the fact that "the melanosis of the mucosa of the large intestine can be clinically diagnosed by means of the rectoscope."

Site of Involvement.—Pick found the entire colon to be involved and commented on the sharp demarcation at the ileocecal valve, the distal portion being pigmented while the proximal side was free. The density of pigmentation varied in different parts of the colon, in some cases being more marked in the cecum and ascending colon, while in others the descending colon was darker. He was impressed by the lack of other pathologic changes in the colon. "Signs of ulceration, scars, inflammatory residue or catarrhal states of proliferation were not found." Other organs were free of abnormal pigmentation.

The entire colon is not always involved, according to subsequent writers. Lubarsch and Borchardt⁷ found the principal sites of deposit in the cecum, appendix and ascending colon. Stewart and Hickman state that "almost invariably the pigmentation is deepest in the cecum and ascending colon, and it becomes less intense on passing down the gut. Very exceptionally the melanosis is more intense in the lower than in the upper part of the intestine; occasionally it is patchily distributed." According to Lignac, the largest amount of pigment is found in the cecum and in the rectum. Several authors (Henschen and Bergstrand,⁸ Lubarsch and Borchardt, Stewart and Hickman) have noted pigmentation in the ileum. Many writers comment on the presence of pigment in the lymph glands of the mesocolon (Lubarsch and Borchardt, Henschen and Bergstrand, Lignac, Stewart and Hickman).

Pigmentation of the vermiform appendix has been frequently described with or without associated pigmentation of the colon. Pick stated that the appendix was usually involved in melanosis coli. In ten of Henschen and Bergstrand's sixty-five cases the pigment was limited to the appendix. Stewart and Hickman state that "melanosis is not infrequently met with in surgically removed appendixes; the naked-eye and microscopic characters are similar to those of melanosis coli." There is some doubt, however, that all the pigmented appendixes are cases of true melanosis, since the pigment was called hemosiderin by Schmidt,⁹ and Battle¹⁰ demonstrated iron in four of his cases (table 1).

Stewart and Hickman frequently found melanosis coli in association with cancer of the colon. In a clinical series of 100 cases of carcinoma of the colon, the incidence of melanosis grossly was 55 per cent. An additional 13 per cent was found on microscopic examination. In autopsy material the incidence was about the same (table 2). The melanosis in these cases was attributed to the concomitant intestinal stasis. It was usually more marked above the growth but was frequently found below it. The incidence of melanosis did not vary to any extent with the location of the cancer. Porter¹¹ reported a case of melanosis of the cecum in association with cancer of the terminal ileum. He quotes a communication from Ewing: "Melanosis is a rare but well known complication of tumors of the cecum and is due to chronic stasis which arises in some of these cases."

Histology.—The pigment is usually confined to the stroma or tunica propria of the mucosa. It lies within large mononuclear cells whose exact nature is unsettled. Pick regarded them as connective tissue cells; Henschen and Bergstrand, as wandering cells of connective tissue or possibly lymphatic origin. Lubarsch and Borchardt, Lignac, and Stewart and Hickman were uncertain of their nature. McFarland¹² called them plasma cells. Writers agree that the epithelial cells are free of pigment.

The appearance of the pigment varies with the degree of pigmentation. In the very early cases, small yellowish-brown granules appear in the cytoplasm (Stewart and Hickman). Later these granules may increase in size and become darker, gradually filling the entire cytoplasm of the cell. Free pigment may be seen, probably due to disintegration of the pigment cells (Lubarsch and Borchardt). While usually limited to the tunica propria, invasion of the muscularis by a few cells has been reported (Henschen and Bergstrand, McFarland, Lubarsch and Borchardt, Stewart and Hickman), and lymphatic involvement is not uncommon. Stewart and Hickman suggest that the melanin may first appear in the superficial zone of the tunica propria and that the pigmented cells may then migrate to the deeper zones of the mucosa. Pick suggested that the fine striations of lighter color were due to ramifications of blood vessels and that the punctate light-colored follicles represented mucosal lymphoid tissue. This opinion has been generally accepted.

Nature and Origin of the Pigment.—Early writers believed that the colonic pigmentation resulted from the ingestion of a heavy metal, either mercury or lead (Williams,¹ Pitt,¹³ Rolleston¹⁴). However, Solger and Pick could demonstrate no heavy metals in chemical analysis of their cases. Virchow¹⁵ was the first to suggest a hematogenous origin as a result of his chemical studies. This theory is still held by many writers (Solger, Neumann,¹⁶ Lignac), and the condition is referred to in many textbooks as hemochromatosis (Lynch,¹⁷ Gant,¹⁸ Rankin, Borgen and Buie,¹⁹

Lockhart-Mummery²⁰). Solger felt that vascular congestion predisposed to pigment formation; hemorrhages into the intestinal tract with subsequent bacterial action were suggested by Lignac, while Lynch postulated a disturbance of the chromogenic function of the liver secondary to bowel infection and toxemia. However, careful chemical analysis has failed to reveal iron in pigment obtained from the colon in the hands of Pick, Solger, Henschen and Bergstrand, and Lubarsch and Borchardt, although the latter state that siderosis may coexist with melanosis. Dalldorf²¹ was unsuccessful in an attempt to produce pigment in a colostomized dog by injections of blood. The limitation of the pigmentation to the colon is likewise difficult to explain if its source is hematogenous.

The possible relationship between the bowel pigment and bile pigments was considered by Solger, but his tests for these substances were negative.

The similarity of the pigment in melanosis and in ochronosis was noted by Lubarsch and Borchardt, but they concluded that "the ochronosis of the cartilage which is observed in alkaptonuria has in all probability no bearing on the pigmentation of the colon." The intestinal mucosa was free of pigment in Goldberg's²² case of ochronosis from the external use of phenol.

The majority of writers feel that the pigment is a true melanin or a melanin-like substance. Pick²³ and Lubarsch²⁴ concluded that the pigment was the same as the melanin found in skin and hair. Lubarsch noted that the usual wear and tear pigment was present in all tissues (epithelium, muscle, nerve) while he believed that the melanin of melanosis coli was present only in connective tissue cells. Hueck,²⁵ Henschen and Bergstrand, Dalldorf, and McFarland classify the pigment as being intermediate between true melanin and wear and tear pigment (lipofuscin), because of slight differences noted chemically between true melanin and pigment obtained from the colon. That such difference of opinion exists is not surprising, since the exact chemical nature of melanin is not known. Percival and Stewart²⁶ recently reviewed the subject of melanogenesis and concluded that it is "probable that there exists a whole series of chemical compounds, more or less closely related, and known to us collectively as melanins. . . . Briefly, then, we may say that melanin is the name applied to a group of nitrogenous substances which contain neither iron nor sulphur as an essential part of the molecule, which may contain various amino acids, and which contain the indole ring." Chemical study has shown that melanin is formed in members of the vegetable and animal kingdoms by the action of a ferment on certain cyclic compounds, such as tyrosine, phenol and pyrogallol (Bertrand,²⁷ von Fürth²⁸). Quattini²⁹ found that the injection of pyrrole, indole and skatol into the skin of rabbits resulted in melanin formation. The chemical nature of the transformation

from chromogen to melanin has been studied by Raper.³⁰ Working with tyrosine and tyrosinase, he isolated an intermediate substance, dioxyphenylalanine, which was easily oxidized to a red pigment and later to melanin. Bloch³¹ called this intermediate substance "dopa." By immersing tissue in a solution of dopa, certain cells were found to have the ability to make melanin. He considered these cells melanoblasts and believed they contained a ferment, which he termed dopa-oxidase. Percival and Stewart confirmed Bloch's work and concluded that "there is convincing evidence . . . that the dopa reaction resembles very closely or is identical with the normal process of melanin formation. The dopa reaction demonstrates the presence within the cell of an oxidase, the reaction of which seems so far to be specific. It is certain that the ferment exists in the melanoblasts, and that any cell which can be shown to contain it may be regarded as capable of producing melanin."

It was Pick's belief that the melanin in melanosis coli resulted from aromatic protein decomposition products of the contents of the colon (indole, skatol) under the influence of an oxidative ferment produced by the connective tissue cells of the mucosa. The ability to produce this ferment was thought to be limited to certain individuals. The association of constipation with melanosis stressed by all recent writers on the subject supports the theory of Pick, which is accepted by Stewart and Hickman, and Henschen and Bergstrand. McFarland suggested that a ferment was formed in the intestinal contents and that pigment was manufactured by such intestinal mucosa as came in contact with and absorbed this ferment. Dalldorf felt that bacterial action in the colon could account for the production of pigment, which was then absorbed by the mucosa.

Laidlow,³² using Bloch's technic previously described, failed to demonstrate cells in the intestine capable of producing melanin in a case of melanosis coli. Many sections of bowel, not pigmented, also failed to show the presence of melanoblasts. This author feels that the pigment is probably derived from ingested food-stuffs and is then phagocytized by the cells of the intestine.³³

ANALYSIS OF CASES

This report comprises a series of forty-one cases of melanosis coli involving the lower part of the colon as determined by sigmoidoscopy.

Incidence.—Reports as to the incidence of melanosis coli on macroscopic examination of autopsy specimens vary from 0.04 per cent (Pick) to 11.2 per cent (Stewart and Hickman) (table 3). Henschen and Bergstrand demonstrated pigment microscopically in 55 of 225 cases (24.5 per cent) as compared with 1.6 per cent by gross examination. In the study of specimens of colon removed at operation for intestinal stasis, McFarland found definite melanosis in 11 of 206 cases (5.3 per cent).

Twenty-six of our cases were found in an active office file containing 960 case records, giving an incidence of 2.7 per cent. Sigmoidoscopic examination was performed in approximately 553 of these cases, giving an incidence of 4.7 per cent of the cases in which the possibility of making the diagnosis was present. Most

patients on whom this examination was performed had varying degrees of colon stasis. In segregating the cases of colon stasis it was found that approximately 53 per cent of the 960 cases could be so classified. The incidence of melanosis in the cases of colon stasis was 5.1 per cent. No other statistics were found in the literature giving the incidence of melanosis as diagnosed by sigmoidoscopy. Lockhart-Mummery, however, estimated that rectal pigmentation occurs in about 1 per cent of patients.

Site of Involvement.—Practically without exception the pigmentation was more intense in the rectum, usually just inside the anal sphincter. In most patients the color of the colon was observed to be less dark the higher the instrument was passed into the sigmoid. In some extreme cases the degree of pigmentation was the same in the rectum and the sigmoid. It is probable that the rectum was not inspected in many of the cases of melanosis reported in the literature in which the diagnosis was based on necropsy or surgically resected material.

Age.—Solger, Pick, Dalldorf, and Henschen and Bergstrand have emphasized that melanosis is found predominantly in older persons. Obviously the age incidence of melanosis determined from autopsy cases cannot be absolutely accurate. Evidence of melanosis clinically in our series was found to be most prevalent during the age periods in which constipation is most frequently encountered in office practice; namely, between the ages of 30 and 60 years. It was present in four patients under 30 years of age.

The age incidence in our forty-one cases follows: from 20 to 29 years, four cases; from 30 to 39 and from 40 to 49, twelve cases each; from 50 to 59, nine cases, and from 60 to 69 and from 70 to 79, two cases each.

Sex.—There was very little difference in the incidence of melanosis in the sexes in the cases of Lubarsch and Borchardt and of Henschen and Bergstrand. Stewart and Hickman reported melanosis in 9.4 per cent of female as compared to 12.5 per cent of male patients. All of Dalldorf's patients were females. Only five in our series of forty-one cases, or 12 per cent, occurred in the male sex. We explain this by the much greater incidence of constipation and the laxative habit among our female patients. Constipation is much less frequent in early and middle life in the male sex. The later age period of reported autopsy cases may explain the discrepancy between the sex incidence in our cases and those just quoted.

Race.—Melanosis is not peculiar to the white race. Two of ten patients seen at the Graduate Hospital were Negroes.

Constipation.—Obstinate constipation was present in every case and with few exceptions was the reason given for seeking medical advice. Of the group of forty-one cases, constipation had been present "always" in fifteen and "for years" in the remainder, except for four cases in which the history dated back approximately one year.

Laxatives.—Only two patients admitted depended on enemas and seven others used enemas or irrigations frequently. The entire group was primarily dependent on laxatives for bowel evacuations. In thirty-five of forty-one cases it was possible to ascertain the type of laxative used (table 5). Cascara sagrada was used either alone or in combination with Alophen, aloin or

rhubarb in twenty-seven cases. In the remaining eight cases, Alophen was used in five, Lady Webster pills in two and compound licorice powder in one case. Many patients admitted taking other laxatives previously but these mentioned were employed for a considerable period previous to the discovery of the melanosis.

In ten cases (29 per cent), the laxative had been used daily for one year or less. The shortest period was four months of the daily use of cascara. However, this individual had taken an unknown laxative pill for twenty years previously. Cascara was the laxative recorded in eight of these cases and Alophen in the remaining two cases. Five patients had used one of the laxatives mentioned from one to five years, six patients from six to ten years and five patients from eleven to twenty-five years. In nine cases the time of using the laxative in question was stated as "years." With the exception of six cases in the entire series, the drug was taken daily. In three of the latter cases the frequency of its use was in doubt and in the other three it was used either two or three times a week.

As far as we have been able to determine, Bartle,³⁴ in 1928, has been the only author referring to a possible relationship between laxative habit and pigmentation of the colon. He described the pigmentation as a hemochromatosis occurring in patients addicted to the use of cascara over long periods of time. Many authors (Cushny,³⁵ Sollmann,³⁶ Bastedo,³⁷ Valaer³⁸) state that cascara, aloes, rhubarb, senna and frangula comprise a distinct group of cathartics that owe their activity to the presence of irritating anthracene or emodin compounds. Cushny says: "The chemical examination of these drugs is a matter of difficulty as they often contain several active principles which are very nearly related to each other, and some of which are undoubtedly the products of decomposition of more complex bodies. All those which have been completely isolated have proved to be derivatives of anthraquinone. All members of the group contain emodins, or trioxymethylanthraquinone." According to Sollmann, Tappeiner and Brandl,³⁹ in 1889, showed that emodins act largely on the large intestine and do not cause any increase in secretion. Roentgen study has substantiated this view (Magnus,⁴⁰ Meyer-Betz and Gebhardt⁴¹). Cushny explains this site of action by assuming that the drugs do not find suitable conditions for solution in the small bowel. Historically, some of these drugs are very old. Sollmann states that rhubarb has been used since antiquity in China and by Roman physicians. Aloes was used in ancient Greece and probably in Egypt, while senna was introduced by the Arabians. Cascara is an American product, having been introduced in 1872 as "Donnelly's Discovery." Bundy⁴² wrote the first scientific article in 1879. In the forms commonly used, all the members of this group are associated with pigment which seems intimately related to the active principles.

It is noteworthy that in every one of our patients with melanosis from whom a laxative history could be obtained, cascara or some other member of this laxative family had been taken practically daily for long periods just previous to the finding of the colonic pigmentation.

Bowel Putrefaction.—Since several authors have mentioned the possible importance of the presence of putrefactive bodies in the colon in the development of melanosis, our cases were reviewed from that standpoint.

(a) A careful dietary history was taken of twenty-eight patients. The daily ingestion of an excessive amount of putrefactive proteins (meat, fish, eggs or poultry) was noted in only one. This class of proteins was taken once or twice daily by nine patients and only once daily by fourteen. Two patients admitted taking putrefactive proteins only occasionally and two others had been following a nonputrefactive diet for two and three years. From a perusal of the records of many other cases of colon stasis without melanosis, we concluded that our patients with melanosis were not using a greater quantity of putrefactive proteins than the average patient with constipation. If the history given by two patients can be relied on, the ingestion of food capable of putrefying in the bowel is not essential to the development of melanosis.

(b) Without entering into a discussion of the indican test as a measure of bowel putrefaction, the feeling at present seems to be that a persistently strong reaction for indican in the urine indicates the presence of putrefaction. It is doubtful, however, if a negative test rules out this condition. The test was performed in twenty-five cases with the following results: negative, 12; very faint, 5; plus 1, 3; plus 2, 2; plus 3, 2, and plus 4, 1. The incidence of indicanuria in this series of patients with melanosis is quite the same as a similar number of cases of colon stasis without pigmentation, reviewed for comparison.

Clinical Survey of Colon.—These cases were reviewed in order to determine the existence of any abnormalities common to the group and consequently of significance in the etiology of melanosis. The type of anal sphincter was recorded in twenty-four cases. Hypertonicity or stricture was noted in eleven cases, or 46 per cent. The sphincter was normal in nine and atonic in five cases, or 21 per cent. The size of the rectum, based on digital examination, was noted in thirty-eight cases. Marked dilatation was present in all but two cases. In spite of the fact that most patients were using large doses of laxatives daily, 75 per cent of them had fecal accumulations in the rectum when digitally examined. Rectal dilatation and proctostasis seemed, therefore, to be an almost constant finding. In twenty-seven of thirty cases the stools originally examined were of mushy or liquid consistency. In many instances, bowel movements did not occur unless sufficient laxative was ingested to produce a soft evacuation. As anticipated, in rectums of this type the incidence of catarrhal proctosigmoiditis was high. In nineteen of twenty-three cases (83 per cent) an excessive amount of mucus was noted at the time of original sigmoidoscopy. The mucus in most cases was described as being of the yellow adherent type rather than clear so-called neurogenic mucus.⁴³

Roentgen Survey.—Barium enema examinations were analyzed in twenty-seven cases. Eighty-five per cent

43. Bockus, H. L.; Bank, Joseph, and Wilkinson, S. A.: Neurogenic Mucous Colitis, *Am. J. M. Sc.* **176**: 813 (Dec.) 1928.

of these patients had the long redundant type of colon. The colon was capable of a sufficient degree of dilatation to record in twenty-two, or 81 per cent. It was most marked in the rectum and sigmoid but in many cases it was present throughout the colon. Spastic phenomena, so commonly encountered in constipation, were strikingly uncommon in this group. Spasticity was noted, often in a comparatively mild degree, in nine cases. It was most frequently present in the pelvic colon. A marked degree of ileocecal incompetence was found in only five cases.

Associated Symptoms.—Constipation may exist for years without giving rise to subjective complaints. Commonly, symptoms develop after the habit of using laxatives, enemas or irrigations has been formed. For this reason and in order to ascertain to what extent the melanosis may be responsible for colonic symptoms, the following analysis is included:

(a) *Abdominal Symptoms:* Obviously it is difficult to determine the mechanism responsible for many vague abdominal complaints if disease is suspected in more than one organ. However, coexisting extracolonic disease was encountered rarely in this group of patients. Symptoms that were thought to arise from the colonic tract were present in thirty of forty-one cases, or 73 per cent. Variable degrees of migratory, generalized or lower abdominal discomfort or pain occurred in seventeen patients. Two patients complained of occasional spells of diarrhea. In eleven cases the symptoms were in large part epigastric, consisting of burning, fulness, pressure sensations, nausea and vomiting.

(b) *So-called Toxic or Constitutional Manifestations:* The incidence of the complaints that are often mentioned in toxic bowel states is given in this group of cases of melanosis. Headache was noted in twenty-seven cases; fatigue, malaise or excessive drowsiness in fourteen; dizziness or vertigo in six; joint pains, "neuritis" or "neuralgia" in five, and insomnia in four cases. A moderate to severe secondary anemia was encountered sixteen times and a count at the lower limit of normal was present in nine cases. In thirteen patients the state of nutrition was recorded as poor. The appearance of the skin was mentioned as being "muddy" or slightly pigmented in twelve patients. Obviously the mechanism responsible for symptoms of this type is difficult and often impossible to determine. However, in most instances no condition other than the bowel stasis could be found to account for their presence. That many of these symptoms were actually dependent on a toxic bowel factor is suggested by their gradual disappearance and the general improvement of the health of the patients after the institution of the type of bowel regimen outlined. It is our feeling that the aforementioned symptoms are dependent on the advanced colon stasis and the concomitant catarrhal colitis coincident thereto rather than on the melanosis per se. The same symptoms occur in severe types of colonic stasis without melanosis.

Effect of Treatment of the Melanosis (table 6).—Twenty-nine patients were treated for constipation under our supervision. All laxatives were discontinued with the exception of magnesium oxide, which was used at the onset in twenty-three cases. Almost as a routine it was prescribed as a powder in combination with kaolin and often with belladonna and calcium. Small doses of liquid petrolatum were used in most instances and agar flakes in about one half of the cases. From one to six tablespoonfuls of lactose was prescribed in

twenty-four cases. The diet during the first few weeks was either entirely devoid of putrefactive proteins (ten cases) or contained only a very small amount of this class of foods. Colon irrigations were not ordered. Enemas were employed at the beginning of treatment in a few cases. The usual advice concerning the necessity for establishing a habit time and the importance of exercise and correction of faults in the manner of living was given.

A number of authors have stated that melanosis coli is permanent. Both Bartle and Lynch, however, have observed a disappearance of the pigmentation. An opportunity was afforded to reexamine the bowel mucosa through the sigmoidoscope after the institution of treatment in eighteen cases of this series. In fifteen, the melanosis had disappeared. The shortest disappearance time observed was four months, in an individual who had been taking cascara daily for ten years. The longest period elapsing between sigmoidoscopic examinations in which the pigmentation was observed to persist was twenty-seven months. This patient, however, was not under close supervision and probably resorted to some of the anthracene laxatives from time to time. However, a third sigmoidoscopy performed five years after the first showed no evidence of pigmentation. In only two others reexamined after a year or more (twelve and fourteen months) was the melanosis observed to be still present. A third check-up in eighteen months and four and two-thirds years, respectively, no longer revealed melanosis of the colon in the two patients.

The time elapsing between sigmoidoscopic examinations in the three patients in whom the pigmentation has not yet disappeared was three weeks, six weeks and four months. The second examination in the first two patients revealed a lessening in the degree of pigmentation and follicular hypertrophy. The third case showed no change after a lapse of four months. From this analysis it is estimated that from four to twelve months is necessary to a complete disappearance of pigmentation of the rectosigmoid in well established cases of melanosis.

COMMENT

An analysis of experimental data summarized from the literature indicates that the pigment responsible for melanosis coli does not contain iron and probably is not associated with any disturbance of sulphur metabolism (Percival and Stewart⁴⁴). We can find nothing to support the view that melanosis is in any way dependent on or associated with hemochromatosis, ochronosis, sulphhemoglobinemia (Harrup and Waterfield⁴⁵) or methemoglobinemia. The pigment apparently belongs to the family of melanins, previously discussed. It lies within the large mononuclear cells in the tunica propria layer of the mucosa but never involves the epithelial cells. Laidlow's inability to demonstrate the presence of melanoblasts in the colonic mucosa favors the theory of phagocytosis from the intestinal lumen rather than pigment manufacture within the mononuclear cells. Laidlow feels that the melanin in the intestine may be derived from foodstuffs. Our review of forty-one cases of melanosis coli diagnosed clinically by sigmoidoscopy discloses that every patient from whom a detailed laxative history was obtained had used habitually for long periods one of the group of

laxatives containing anthracene or emodin compounds. The laxative effect of this group of drugs is due to their irritant action on the large intestine. They are highly complex, containing resinous substances. In the forms usually dispensed, they contain some pigment which seems intimately related to the active principle. It seems highly probable that the anthracene laxatives either contain a pigment or elaborate a pigment within the colon which is phagocytized by the deep mucosal cells causing melanosis coli. Whether melanosis coli can develop in individuals who have not taken any of the anthracene laxatives, it is impossible to state. The use of some of the laxatives in this group dates back to antiquity.

The question might be fairly raised that the history of the use of the anthracene laxatives in these cases is entirely incidental, since this group of drugs is used so commonly in constipation. For this reason, we analyzed the case records of 300 patients whose bowels were constipated on whom sigmoidoscopic examinations had been carried out who did not show melanosis and found that thirty-seven patients, or 12.3 per cent, used one of the anthracene laxatives, the remainder relying on other laxatives, cathartics or enemas. We feel that obtaining a history of the use of anthracene laxatives in 100 per cent of thirty-five cases of melanosis and of only 12.3 per cent of persons whose bowels were equally constipated without melanosis is significant of the importance of this family of laxatives in the etiology of melanosis. An analysis of the group of thirty-seven patients addicted to anthracene laxatives without melanosis does not definitely reveal the cause for their failure to develop pigmentation. As a group, the laxatives were used less frequently, or the information concerning their frequency was not available. The constipation seemed just as marked and catarrhal changes in the bowel were found with equal frequency. They did seem to be more addicted to the use of enemas or irrigations.

The principal predisposing factor in the development of melanosis is probably undue stasis of intestinal contents. This may explain its high incidence in cases of cancer of the colon and in resected appendixes. The obstinate constipation in our cases was almost always associated with observations indicative of long-standing proctostasis permitting of prolonged contact of the mucosa with any pigment that might be resident within the rectosigmoid. It is also of interest that these patients were not given to "flushing" the colon either with enemas or with irrigations. The history of constipation of only one year's standing in four cases serves only to emphasize the primal importance of the laxative habit in the etiology. We doubt whether bowel putrefaction per se is responsible for melanosis. The possibilities for the development of putrefaction were slight in many cases, and crude laboratory tests for putrefaction were frequently negative. Although histologic examination of melanotic bowel material has failed to reveal any signs of marked inflammatory changes, the sigmoidoscopic examination of 83 per cent of our cases suggested the presence of a concomitant catarrh, probably induced by the laxatives used. Whether the associated catarrh may have preceded or actually encouraged the deposition of the pigment it is impossible to state.

SUMMARY

1. The literature of melanosis coli has been reviewed particularly from the standpoint of the nature, origin

and chemistry of the pigment and the manner of its deposition in the mucosa.

2. Previous reports on melanosis coli are based on material removed at operation or autopsy. In spite of the striking picture presented through the sigmoidoscope, we have not encountered a comprehensive study of the condition based on a proctosigmoidoscopic diagnosis in the literature. A series of forty-one cases so diagnosed is analyzed.

3. Melanosis coli was diagnosed in 4.7 per cent of 553 patients subjected to sigmoidoscopic examination, the great majority of whom were so examined because of colon stasis.

4. The pigmentation when not uniformly distributed was always more intense in the rectum; gradually fading out in the upper sigmoid in many cases.

5. The age incidence corresponded to the age period in which constipation was most frequently encountered among our patients; namely, between 30 and 60 years. Eighty-eight per cent of the patients were women.

6. Obstinate constipation of years' standing was noted in all but four patients whose bowels had been constipated for only one year.

7. A laxative history in thirty-five cases fails to show a single case in which one of the anthracene laxatives, usually cascara, had not been used for long periods immediately preceding the finding of the melanosis.

8. Detailed study of the colon in these cases indicates the existence of an extreme degree of proctostasis which permits of contact with contained pigment material over long periods. A concomitant catarrhal proctosigmoiditis was usually found. It is felt that bowel putrefaction per se is not responsible for the pigmentation.

9. The high incidence of abdominal and so-called toxic symptoms encountered in these cases was probably dependent on the associated colonic stasis and catarrhal colitis rather than on the melanosis coli.

10. The pigmentation of the colon herein described is not permanent. Stopping the laxative and instituting a colon stasis regimen caused the pigmentation to disappear in fifteen of eighteen cases. From four to twelve months is apparently necessary to its complete disappearance.

250 South Eighteenth Street.

Maturity and the Whole Personality.—In recent years psychiatry has recognized the importance of a study of the personality and has tried to determine its share in the psychotic reaction from the point of view of personality reactions. By personality I mean the psychobiologically integrated unit which has developed and is developing during life. One can see an increasing organization of the personality from infancy to maturity, but not all personalities reach full organization, and in many people certain aspects of the personality are less organized or integrated. In the feeble-minded group there is primarily a lack of organization of the intellectual aspect. In other types of psychopathic make-up, other parts of the personality may be less developed and organized. Physical and mental development in the broadest sense are not parallel. It is also known that some organs of the body develop sooner than others. One speaks of maturity, therefore, when the whole personality has reached a degree of organization which harmonizes the various strivings with integration of emotional and intellectual resources, utilizing the experiences of the past and adjusting imagination and anticipation to reality.—Diethelm, Oskar: Nonorganization and Disorganization of the Personality During Psychoses, *Arch. Neurol. & Psychiat.* 29:1289 (June) 1933.

THE SURGICAL TREATMENT OF
ARTERIAL EMBOLISM

ARTHUR A. ZIEROLD, M.D.

MINNEAPOLIS

The history of the surgical treatment of arterial embolism is a comparatively short one. This is somewhat difficult to explain in view of the fact that the principles of vascular surgery have been developing since the time of John Hunter. The first surgeon of record to attempt to remove an embolus by arteriotomy was Ssabanejew.¹ In 1895, because of the impending gangrene of a leg, he opened the femoral artery and endeavored to remove the embolus. He was not successful, and after amputation of the leg the patient died. The first completely successful operation was performed by Labey² in 1911, when he removed an embolus from the femoral artery six hours after the occurrence of symptoms. The chronology of attempt and success is detailed at length in the article which Einar Key³ wrote in 1921. At this time, Key reported the first series of importance, and it is on the encouragement afforded by this report that this phase of vascular surgery so promptly and vigorously grew. In 1928, the literature of the subject was again reviewed by Petitpierre,⁴ who was able to assemble 118 cases. From this time to the present there have been frequent additions, but the total reported is made up mostly of groups of two and three cases. Because of this, and of the diversity of individual judgment and procedure, analysis of results and observations is difficult.

With the idea in mind that larger individual series might be worthy of record purely as statistical material, I am reporting a series of twenty cases of arterial embolism that have come under my observation. All but two of these cases come from the wards of the Minneapolis General Hospital. Through the careful supervision of Dr. George Fahr, chief of the medical service, and his associates, it has been possible to collect a relatively large series during the space of three years. While the number of cases is yet too small to serve as the basis of any very critical analysis, nevertheless, a few general conclusions may be drawn.

With the exception of rare instances of detached atheromatous plaques, the larger animal parasites or artificially introduced foreign bodies, arterial emboli have their origin in cardiac thrombosis. Bull,⁵ in a survey of the material at the Riks Hospital, found fifteen cases of arterial embolism in 6,140 autopsies. Of these, thrombus formation in one or more of the cardiac cavities could be demonstrated in thirteen. It is true, of course, that thrombosis may occur at other points in the vascular tree, but as these are not so easily subject to dislodgment they furnish a much less frequent source of embolism.

Welch⁶ and later Aschoff and Fåhræus⁷ showed that three factors are involved in the development of a

thrombus; viz., a change in the surface of the vessel wall, changes in the physicochemical constitution of the blood, and a local change in the rate of flow. Of these, the last factor is perhaps the most potent. From these data it is readily seen that the heart chambers during the stage of derangement offer the ideal site for thrombus formation. In the presence of at least two of these three factors, thrombus formation is begun by the precipitation and the agglutination of blood platelets at some point on the endothelial surface. As the process grows, first red cells become entangled and later white cells. Eventually, the endothelial cells become injured, fibrin ferment is liberated and fibrin results, which aids in the organization and rapid enlargement of the mass. In this manner, the first to develop is a red thrombus, so called because of the preponderance of red cells, and finally the mature structure, the white thrombus, which owes its appearance to a superabundance of leukocytes. The distinction between red, white and mixed thrombi is the age and the state of development as well as the constitution. This is of importance in the light of subsequent developments related to embolism.

Distribution of emboli reported in this series.

When a thrombus arises within the heart cavity, by reason of rate of growth and disproportion between surface attachment and mass, it frequently becomes dislodged by the agitation of the disorganized heart mechanism. The detached mass passes into the arterial circulation as an embolus. As the diminution in caliber of the arteries is not a constant and uniform one but is most abrupt and distinct at points of major bifurcation, emboli tend to lodge in these localities. When such lodgment occurs, the irritation caused results in a constrictor spasm, which more or less completely occludes the lumen. This spasm extends distally and is probably the origin of the initial pain of which the patient complains at the onset. Although this is undoubtedly augmented by the pain of the anoxemia that follows, it is only on the existence of the extensive spasm extending peripherally that the failure of coincidence in location of pain and embolus can be explained. Because of the irregular outline of most emboli, obstruction of the circulation is not immediate. As a result, there is a local disturbance of blood flow with the attendant factor of irregularity of surface, providing for the development of a secondary thrombus. Accordingly, there grows distally in the direction of the blood stream a secondary thrombus, which corresponds to the "schwanzteil" described by Aschoff. This may vary from one of a few centimeters to one of great length. Nyström⁸ has reported a secondary thrombus, 86 cm. in length. Thrombosis does not occur proximally for more than a few millimeters, and the problem of retrograde thrombosis, in the absence of generalized sepsis, does not arise. Eventually, the affected artery becomes completely occluded, either at the point of lodgment of the embolus or by

secondary thrombosis throughout its length. It is probable that the completeness with which an artery is occluded at the time an embolus lodges is of far greater importance in the failure of extensive secondary thrombosis development than the lapse of time following the occurrence of embolism.

After the initial blanching of the extremities, which is due to arterial spasm rather than to complete obturation, the skin assumes first a dusky hue and then a bluish mottling, which is attended by coldness and frequently by loss of superficial and deep sensibility. If the upper portion of a major vessel is involved, the tendon reflexes are frequently lost. The end-result is gangrene to a level determined by the collateral circulation. It is toward the development of such gangrene that treatment is directed. Key, Nyström and others have mentioned and, with reservation, have advocated the employment of massage with the idea of dislodging and forcing the obstruction distally to such point as circulation could be maintained by the collateral supply, and, while this procedure is apparently feasible and is supported by several reported cases, it is not the procedure of choice in the majority of instances.

The surgical treatment of arterial embolism consists in the exposure of the affected vessel at the site of obstruction and the removal of the obstructing embolus and thrombus by arteriotomy. In the twenty cases that I have had under my observation, I have performed this operation eleven times. The material here presented consists of eleven surgical cases and eight which were considered nonsurgical. In one case, which remains unclassified, the femoral vein was ligated and the artery was not opened. Although the procedure terminated successfully, it is not included in the operated group.

The cases were distributed equally between males and females. The age of incidence is that at which a break in cardiac compensation most frequently occurs, namely, between the sixth and seventh decade, the corrected average being 65 years. Of the total number of cases under observation, fifteen presented definite histories of previous cardiac disorder. An attempt was made to determine the duration of cardiac disease previous to the onset of embolism, but these observations varied within such wide limits that no causal time relations could be established. There were four patients without previous or existing heart disease who developed arterial emboli in the presence of generalized infection. The one remaining case to be accounted for developed spontaneously in the absence of any other demonstrable disease process. The preponderance of cases of cardiac origin is in accordance with the literature and tends to confirm the belief that the most important factor in the development of thrombosis is a local disturbance in the velocity of blood flow.

The symptoms and signs of embolism itself were uniform in character but varied considerably in degree and location. In all cases, sudden severe cramplike pain was the outstanding feature of onset. The location of this pain was invariably at some point distal to the arterial obstruction and was of no value in localization other than to identify the extremity involved. The later developing anesthesia was variable in extent, depending on the adequacy of the collateral circulation, and was equally valueless as a localizing symptom.

Of the objective signs, pallor, coldness and subsequent discoloration, while corroborating the diagnosis of embolism, were as confusing as the subjective symptoms when by their aid alone an attempt was made to

identify the exact point of lodgment, as they too were dependent on the immediate degree of occlusion of the artery, the extent of development of secondary thrombosis, and the adequacy of collateral circulation. Gangrene in no instance extended beyond the middle third of the calf. This was equally true of the nonoperative cases and of the operative ones. The most valuable finding was the presence or absence of pulsation in the affected vessel. This definitely located beyond question the exact point of obstruction. In the earlier cases of this series, an oscillometer was used to determine the presence or absence of pulsation, but the results were so modified by the collateral circulation as to be confusing, and for this reason it was abandoned. The observations at autopsy and at operation proved the wisdom of this course. It was found that the majority of emboli lodge in the vessels of the lower extremities, only two being found in the arm, both of these occurring in the right axillary vessel. There appears to be no predilection for one side or the other, the two being about equally affected. Of the operative cases, the left lower extremity was affected seven times and the right three, but in so small a number of cases this cannot be considered of great importance. In our series, the point of most frequent occurrence is in the lower portion of the femoral artery where it passes through the adductor muscle to enter the popliteal space. The next common site is at the branching of the profunda femoris. It is worthy of note that in every instance of embolism the point of lodgment was at the branching of a major vessel. With this fact in mind, together with an accurate observation of the presence or absence of pulsation, one can make a definite estimate of localization by inference alone.

A consideration of the end-results in both the non-operative and the operative cases is interesting, but by reason of the nature of the material, as well as of its amount, the conclusions arrived at must be correspondingly tentative. Of the total number of cases here presented, operation was not performed in eight, while eleven operations were performed in the remaining ten. The division of the material is an arbitrary one and not dependent entirely on judgment as to operability. This is of importance, as it affords comparison between selected and unselected material. Much has been written as to the necessity for early operation, and there can be no question that operation soon after the lodgment of an embolus not only makes its removal easy but also avoids the complicating injury to the vessel wall and secondary thrombosis. In this series, the lapse of time between the initial symptom and the operation varied from one and one-half hours to seventy-two hours, in all but three the time being twelve hours or more. Nevertheless, of the eleven patients, the circulation was restored in eight, including one at thirty-six hours and one at seventy-two hours. This would indicate that other factors such as blood pressure, velocity and the completeness, and location of the obstruction were of greater importance in determining the prognosis. While it was possible to restore the circulation, and by this I mean not only pulsation in the immediate neighborhood of the arteriotomy but also warmth and color to the extremities, in eight of the patients, unfortunately only three survived to be discharged from the hospital. This rather gloomy outlook is somewhat lightened by observations on the patients who were not operated on. Of these, seven, or 87.5 per cent, died within a period of from one to fourteen days following the initial symptoms of embolism. It is of interest to

note that the length of survival in the two groups is much the same, which would give some basis for the statement that surgery in itself is not properly responsible for the mortality in this form of treatment. As the end-result of the two series shows an 87.5 per cent mortality in the cases in which operation was not performed and a 72.7 per cent mortality in the cases in which it was performed, with a corresponding 72 per cent of immediate restoration of circulation, it would appear that embolectomy is a proper and reasonable undertaking. In the light of the experience as represented in the foregoing data, I believe that the following conclusions are sound.

Arterial embolism is not an uncommon phenomenon and should be considered as a possible complication of cardiac derangement. Multiple emboli, although occurring at intervals, are not sufficiently frequent to exclude consideration of surgical treatment. In the diagnosis of this condition, age, sex and physical conformation are of little importance. The most common and outstanding element of the previous history is cardiac disease, attended by auricular fibrillation. The cardinal presenting symptoms are those of sudden cramplike pain in an extremity, followed by pallor, then cyanosis and coldness, and terminating in loss of sensation. The most frequent site of localization is the lower portion of the femoral artery. The localization of the pain and the subsequent limits of pallor, discoloration, coldness and anesthesia may serve to identify the extremity affected but are of little value in determining the exact point of lodgment of the embolus. Localization is best attained by palpation of the suspected vessel.

The prognosis of the individual case depends primarily on the status of the underlying disease process. It is not advisable to subject every patient to operation even though his general condition is good. The collateral circulation of the extremities is such that emboli lodging in the brachial or even in the axillary artery are attended with more than an even chance of recovery without operation. Likewise, emboli lodging at the bifurcation of the popliteal vessel will not require surgery. In fact, many of the successes attributed to operation at this site are probably due to an adequate collateral circulation.

Aside from specific medication, preliminary treatment should be directed toward maintaining blood pressure and velocity of blood flow, as it is on these factors in part that the success of the operative procedure depends. For this reason, local anesthesia is the method of choice. The incision should be made over the artery at the first major bifurcation below the point of definite pulsation. The vessel should be carefully isolated and not lifted from its bed. Because of the attached secondary thrombus invariably present, pressure should not be made on the vessel distal to the embolus. It will be noted that above the embolus the vessel is round, distended and pulsating, and at the lower limits of pulsation the firm mass of the embolus can be easily palpated. Below this point the vessel will be somewhat constricted, depending on the thickness of the wall and the degree of sclerosis present. Before the artery is incised, it should be grasped, proximal to the embolus, firmly by the fingers of an assistant and not by a clamp of any kind, as this tends to injure the walls even though carefully applied. The wound is then flooded and sponged with sodium citrate solution to inhibit coagulation, and an incision one-third longer than the diameter of the vessel is made directly over the embolus. If the embolic mass does not promptly extrude,

it may be teased out with fine forceps, the back pressure of the peripheral vessels being allowed to force out the long tail portion of the attached secondary thrombus. Only when this is complete and there is a free flow of blood, indicating a successful removal, may the artery be grasped below the point of incision. When the flow of blood from above and below the incision is controlled, the wound is approximated, edge to edge, by fine silk arterial sutures.

If a mistake in diagnosis has occurred, and the exact site of the embolus has not been identified, and the mass presenting through the incision in the arterial wall is red and soft, indicating that only the secondary thrombus is accessible, only such portion as lies distal to the opening should be removed and the wound closed. A second arteriotomy should then be performed at the next major bifurcation above this point.

Attempting to remove an embolus and attached thrombus from a point below the site of impaction is difficult and not often successful. For this reason, in embolism of the aorta or iliac vessels direct approach through the abdomen is preferable to the retroperitoneal route. Because of the difficulty I have experienced in dislodging emboli, even with direct exposure, any procedure such as massage or the milking of a vessel distally from the point of obstruction seems not only an illogical procedure but one inviting disaster. Following completion of the operation, the extremity should be placed at rest and kept warm. In the event of gangrene, nothing is to be gained by early amputation. In no case have I seen gangrene extend higher than the middle third of the calf, and I believe that in no instance has the patient been jeopardized by allowing demarcation to become well established.

CONCLUSION

As others have said, there is no simple operation in surgery so eminently satisfactory or attended by such potentiality for good as arteriotomy for arterial embolism.

649 Medical Arts Building.

THE UNCONTROLLABLE CAUSES OF DEATH IN DIABETIC COMA

HERMAN LANDE, M.D.
NEW YORK

The vital statistics of New York City show that the standardized death rate of diabetes has risen from 17.3 per hundred thousand in 1901 to 27.9 per hundred thousand in 1931. The introduction of insulin in 1923 was accompanied by a slight recession in mortality which has since been entirely lost. The beneficial effect of insulin has been manifested only in the lower age periods up to 35 years. From 35 to 44 years the curve has flattened out and above that age the diabetic death rate, particularly in women, has sharply risen. The cause of this increasing mortality despite the use of insulin is today the subject of widespread investigation from which no definite conclusions can as yet be drawn. I have therefore undertaken an analysis of the cases of diabetic coma in the adult wards of the Mount Sinai Hospital for the insulin period 1923-1933 in the hope of throwing some light on this phase of the problem.

The syndrome of diabetic coma is characterized by certain definite clinical and laboratory features, the most

characteristic of which are Kussmaul breathing and an alkali deficit. The definition of diabetic coma is not satisfactorily resolved by identifying it with acidosis. The state of unconsciousness is only roughly related to the reduction of serum bicarbonate. Consciousness may be retained with an extremely low carbon dioxide combining power of the blood. There may be persistent stupor and coma with the blood alkali well above the generally accepted critical levels. In other conditions, alkali deficits of the magnitude occurring in diabetic acidosis are not necessarily attended by a similar syndrome. There is little evidence to incriminate the mild anesthetic action of the acetone bodies. There is no correlation between the concentration of ketones in the blood and the profundity of coma.

I have endeavored, as far as possible, to limit the cases to those with carbon dioxide combining power of the blood below 20 volumes per cent, but the following instances are cited to show the difficulties of rigid classification:

CASE 1.—A woman, aged 56, was admitted in profound coma. The urine contained 2.5 per cent dextrose and large quantities of acetone and diacetic acid. The blood sugar was 280 mg. and the blood carbon dioxide was 20 volumes per cent. Insulin therapy was ineffective, the blood sugar rose to 470 mg. and she died in eighteen hours. The carbon dioxide combining power of the blood, determined ten hours and sixteen hours after admission, was 20 volumes per cent on each occasion. Autopsy revealed no cause for death other than diabetic coma.

CASE 2.—A woman, aged 50, with a three years history of diabetes, was admitted in deep stupor. The urine contained 8 per cent dextrose and a small amount of acetone. The blood sugar was 600 mg. The carbon dioxide combining power of the blood was 43 volumes per cent on admission and 51 volumes per cent when determined two hours later. Because of these figures the patient was not treated, although there was no other detectable etiologic factor; she died in circulatory collapse. Unfortunately, a postmortem examination was not obtained, but the free excretion of 8 per cent dextrose in the urine in association with a blood sugar of 600 mg. suggested that diabetes was the most likely cause of coma.

I have therefore selected the cases of diabetic coma which satisfied most of the essential criteria and which permitted no other diagnosis, either clinically or pathologically. On this basis, I have collected eighty-two reports of cases from the adult wards of the Mount Sinai Hospital for the period 1923-1933. Of this number, twenty-four patients could not be saved, a mortality of 29 per cent. This mortality is partly due to complications in themselves fatal, to the fact that some patients were admitted too late for effective treatment, and, in two early instances, to frankly inadequate insulin dosage. There are, however, a sufficient number with fatal outcome in which adequate supportive and specific therapy was given to prevent me from considering diabetic coma a closed problem.

The therapy of diabetic coma in this institution has not differed essentially from that practiced elsewhere. Gastric lavage, a cleansing enema and the usual supportive procedures have been part of the routine. Fluids have been administered as liberally as possible by mouth, and if fluids were not retained they were given by rectum, subcutaneously and intravenously. The average insulin dosage administered in the fatal cases was 174 units in twenty-four hours, against an average of 124 units for the first twenty-four hours in the nonfatal cases. Although these figures are lower than those used by many others, it is well to remember that many fatalities occurred within a few hours after admission. We have believed it advisable to give from 1 to 2 Gm. of dextrose with each unit of insulin.

Race and sex were not important as determining factors in prognosis. In 88 per cent of the fatal and 86 per cent of the nonfatal cases the patients were Jews. In 64 per cent of the fatal and 68 per cent of the nonfatal cases the patients were females. As may be seen from the accompanying table, however, age had an unquestionable influence on the mortality rate.

It is to be noted in this connection that Joslin reported a negligible mortality in juvenile diabetic coma. There has been only one death from this cause in the pediatric service of the Mount Sinai Hospital in the last six years. It is evident that in large part the high mortality rate reported in this paper is due to the age incidence and the elimination of juvenile diabetes from our statistics. There were only six deaths in our forty-nine cases of diabetic coma in patients under the age of 40, a mortality of 12 per cent; whereas we lost eighteen of our thirty-three patients over this age, a mortality of

Age Incidence

| Age | Number of Cases | Number of Fatalities |
|---------------------|-----------------|----------------------|
| 14 to 20 years..... | 10 | 2 |
| 21 to 30 years..... | 16 | 3 |
| 31 to 40 years..... | 14 | 1 |
| 41 to 50 years..... | 12 | 6 |
| 51 to 60 years..... | 14 | 7 |
| 61 to 70 years..... | 6 | 4 |
| 71 to 80 years..... | 0 | 0 |
| 81 to 90 years..... | 1 | 1 |

54 per cent. These figures help one to understand the vital statistics of New York City, which show that the introduction of insulin has favorably affected the mortality of diabetes only in the group under the age of 35 years.

For the purpose of more detailed analysis, I have divided the fatal cases of diabetic coma into four groups:

Group 1. Cases not adequately treated.

Group 2. Cases in which the diabetic coma was associated with conditions fatal in themselves.

Group 3. Cases in which diabetic coma was the prime cause of death, with associated conditions as contributory factors.

Group 4. Cases of uncomplicated diabetic coma.

The first two groups may be briefly presented:

GROUP 1

These patients entered the hospital early in 1923, when there was a limited supply of insulin available.

CASE 3.—A woman, aged 54, with an eight years history of diabetes, entered in profound coma. The blood sugar was 440 mg. and the carbon dioxide of the blood was 9 volumes per cent. The patient was given 37 units of insulin but did not recover consciousness and died in circulatory collapse.

CASE 4.—A woman, aged 52, with an eighteen months history of diabetes, went into coma twenty-four hours before admission. She was in profound coma; breathing was Kussmaul in type and there was evidence of a bilateral bronchopneumonia. She was given 37 units of insulin but did not respond. Her temperature steadily rose to 105 F. and she died at the end of twelve hours.

GROUP 2

CASE 5.—A woman, aged 82, with an eight years history of diabetes, had had a gangrenous foot for several weeks. The patient went into coma twenty-four hours before admission and entered in a state of stupor with a blood sugar of 300 mg. and a blood carbon dioxide of 18 volumes per cent. Adequate fluids were given by gavage and by rectum, and 150 units of insulin was administered daily. Although the carbon dioxide of the blood rose to 29 volumes per cent, the patient never fully regained consciousness and died on the fourth day. Death and persistent coma were attributed to cerebral arteriosclerosis.

CASE 6.—A man, aged 24, with a one year history of diabetes, had suffered from an extensive furunculosis for one week. He went into coma twenty-four hours before admission and entered the hospital in a semiconscious state with Kussmaul breathing, a blood sugar of 380 mg. and a blood carbon dioxide combining power of 14 volumes per cent. In the course of the first twenty-four hours the patient was given 2,200 cc. of fluids, 240 Gm. of dextrose and 90 units of insulin. He recovered consciousness and after the first day the carbon dioxide combining power of the blood was always above 30 volumes per cent, but he died suddenly on the fourth day in circulatory collapse. Autopsy revealed a generalized staphylococcic infection with metastatic foci in the lungs and subcutaneous tissues.

CASE 7.—A woman, aged 45, with a two years history of diabetes, went into coma twenty-four hours before admission. She was in profound stupor with a blood carbon dioxide combining power of 16 volumes per cent and a blood sugar of 322 mg. There was definite clinical evidence of meningitis and on lumbar puncture purulent fluid was obtained that contained pneumococci. There was no response to treatment and the patient died in twelve hours. A postmortem examination revealed an acute mastoiditis and a purulent meningitis.

CASE 8.—A man, aged 47, with a three and a half years history of diabetes, had had attacks of angina pectoris over a period of nine months. For three days the diabetes was satisfactorily controlled on a diet of 100 Gm. of carbohydrate, 60 Gm. of protein, and 100 of fat, with 40 units of insulin daily. An electrocardiogram showed no definite changes. On the night of the fourth day the patient suddenly went into profound coma with typical Kussmaul breathing. In the course of the next nine hours he was given 8 ounces of orange juice by mouth, 500 cc. of 5 per cent dextrose intravenously and 115 units of insulin. He had recovered consciousness, when he died suddenly as the result of a coronary thrombosis.

CASE 9.—A man, aged 58, with a one year history of diabetes, suddenly went into coma four hours before admission. He was in profound shock with a blood sugar of 400 mg. and a blood carbon dioxide combining power of 12 volumes per cent. He died within a half hour. At autopsy, an acute tuberculous bronchopneumonia was found.

CASE 10.—A man, aged 62, with a four years history of diabetes, had been in coma for three days. On admission he was in profound shock; the urine contained 4.5 per cent of dextrose and large quantities of acetone. The blood sugar was 255 mg. and the carbon dioxide combining power of the blood was 20 volumes per cent. There was no response to treatment and the patient died in two hours. At the postmortem examination there was an extensive tuberculosis of the left upper lobe with gangrenous cavitation.

CASE 11.—A man, aged 53, was known to have diabetes for one month. One week before there had developed a multiple abscess in the thigh that had been associated with increasing drowsiness. On admission, the patient was semistuporous and breathing was Kussmaul in character. The blood sugar was 480 mg. and the carbon dioxide combining power of the blood was 18 volumes per cent. He was given 2,000 cc. of saline solution subcutaneously, 100 Gm. of dextrose, and 340 units of insulin. There was no response to treatment; the temperature rose steadily from 100 to 105.8 and he died twenty hours after admission. Autopsy revealed an acute splenic tumor, and death was attributed to sepsis.

CASE 12.—A woman, aged 21, a Puerto Rican, had no previous history of diabetes. For twenty-four hours before admission she had complained of nausea, vomiting and abdominal pain and had gone into coma two hours previously. She was extremely dehydrated and in profound stupor. The deep reflexes could not be elicited and breathing was Kussmaul in type. Her blood sugar was 120 mg. and the carbon dioxide combining power of the blood was 10 volumes per cent. The urine contained a trace of acetone and 2 per cent of dextrose. She was given a continuous intravenous drip of 5 per cent dextrose in saline solution and in the course of twelve hours received 2,100 cc. of this solution and 160 units of insulin. She remained in coma in spite of the fact that the urine became acetone free. Her circulatory condition became steadily worse. The blood pressure, which was 134 systolic and 84 diastolic, at first dropped to 120 systolic and zero diastolic and then to 84

systolic and 20 diastolic. Her pulse became imperceptible, the extremities cold and cyanotic and the patient died in shock twelve hours after admission. Autopsy revealed a tuberculous bronchopneumonia.

GROUP 3

CASE 13.—A man, aged 48, with a three months history of diabetes and a carbuncle of the neck of seven days' duration, went into coma twelve hours before admission. He was semiconscious with typical Kussmaul breathing. His pulse was weak and thready, the extremities were cold, and the clinical picture was that of shock. His blood sugar was 580 mg. and the carbon dioxide combining power of the blood was 10 volumes per cent. In the course of twelve hours he was given 1,900 cc. of saline solution intravenously and by rectum, 100 Gm. of dextrose and 70 units of insulin. At the end of nine hours the blood sugar had dropped to 350 mg. and the carbon dioxide combining power of the blood had risen to 31.4 volume per cent. He remained comatose, however, and in spite of the improvement in blood figures his vasomotor collapse became more profound and he died in pulmonary edema at the end of twelve hours.

CASE 14.—A woman, aged 63, with a one year history of diabetes, had had an abdominal sinus secondary to an empyema of the gallbladder for six months. On admission, the blood sugar was 300 mg. and the carbon dioxide combining power of the blood was 30.9 volumes per cent. For eight days she remained sugar free on a diet of 40 Gm. of carbohydrate, 50 Gm. of protein and 120 Gm. of fat, without insulin. On the ninth day she suddenly went into profound coma. The blood sugar rose to 480 mg. and the carbon dioxide combining power of the blood dropped to 15.5 volumes per cent. She received 1,000 cc. of 5 per cent dextrose by rectum and 120 units of insulin. Her temperature steadily rose to 106; there was absolutely no response to treatment, and she died in eighteen hours without recovering consciousness. Autopsy revealed a terminal bronchopneumonia as the probable cause of the hyperpyrexia.

CASE 15.—A man, aged 47, with a six months history of diabetes, had had an acute respiratory infection for one week. He was admitted in deep coma from which he could not be aroused. The blood sugar was 250 mg. and the carbon dioxide combining power of the blood was 11 volumes per cent. Within nine hours he received 1,800 cc. of saline solution by rectum and by vein, 125 Gm. of dextrose and 125 units of insulin. There was no response to treatment at any time, and he died in nine hours in profound vasomotor collapse. A postmortem examination revealed a lobar pneumonia involving the right lower lobe.

CASE 16.—A man, aged 60, with a two months history of diabetes, had vomited for two days and entered in profound coma. He was markedly dehydrated, his pulse was barely perceptible and his extremities were cold and cyanotic. Breathing was Kussmaul in character. He was given 1,200 cc. of 5 per cent dextrose intravenously and 110 units of insulin. Under this treatment his blood sugar dropped from 500 mg. to 90 mg. and the urine became acetone free. He remained in a state of profound shock from which he could not be aroused and died in ten hours. Autopsy revealed a purulent mastoiditis and atrophy of the pancreas. Death was attributed to diabetic coma.

GROUP 4

CASE 17.—A youth, aged 17, with a two months history of diabetes, lapsed into coma eight hours before admission. When seen, he was in deep stupor; his breathing was Kussmaul in character, his blood sugar 640 mg. and the carbon dioxide combining power of his blood 12 volumes per cent. After 300 units of insulin, his blood sugar had risen to 760 mg. At the end of eight hours he had received 600 units of insulin, his blood sugar was 420 mg., and he was definitely out of coma. After one hour, his temperature began to rise and before he died, two hours later, it had reached 106, further insulin being absolutely ineffective. Autopsy revealed atrophy of the pancreas but no other cause for the coma or the terminal hyperpyrexia.

CASE 18.—A woman, aged 55, with a six years history of diabetes, had been semicomatose for two days. On admission, she was stuporous and markedly dehydrated. Her blood sugar was 600 mg. and the carbon dioxide combining power of her

blood was 21 volumes per cent. She was given 2,500 cc. of fluids, 175 Gm. of dextrose and 140 units of insulin, and at the end of twenty-four hours she completely recovered consciousness. The carbon dioxide combining power of the blood had risen to 41.6 volumes per cent and she seemed well on the way to recovery when, on the third day, she suddenly lapsed into coma with profound vasomotor collapse; she became cold, pulseless and cyanotic; her blood urea rose to 43.7 mg. and she died in four hours.

CASE 19.—A woman, aged 41, with an eight years history of diabetes, suddenly lapsed into coma two hours before admission. She was in profound stupor; the deep reflexes could not be elicited and her breathing was Kussmaul in character. Her blood sugar was 318 mg. and the carbon dioxide combining power of her blood was 12 volumes per cent. She was given 1,800 cc. of fluids, 100 Gm. of dextrose and 120 units of insulin, but there was no response to treatment. Her temperature steadily rose to 105.8 and she died twelve hours after admission without recovering consciousness.

CASE 20.—A woman, aged 56, with no previous history of diabetes, had been acutely ill for two days and was admitted in a stuporous irrational state. Her blood sugar was 280 mg. and tests of the carbon dioxide combining power of the blood, repeated three times in the eighteen hours she lived, were 20 volumes per cent. She was given 2,800 cc. of fluid, 180 Gm. of dextrose and 160 units of insulin, but treatment was ineffective. The temperature steadily rose to 106 before death. A postmortem examination revealed no cause other than diabetic coma to account for her death or for the terminal hyperpyrexia.

CASE 21.—A woman, aged 42, with no previous history of diabetes, was admitted with a mild tonsillitis. The urine contained 8 per cent dextrose and a small amount of acetone. On the following day she developed acidosis and went into coma. Her blood sugar was 500 mg. and the carbon dioxide combining power of the blood at the onset of coma was 21.4 volumes per cent. She was given 1,000 cc. of saline solution intravenously and 1,000 cc. by rectum, 50 Gm. of dextrose and 280 units of insulin. There was no response to treatment. In the six hours before death her temperature rose from 99 to 105, and she died nine hours after going into coma.

CASE 22.—A woman, aged 24, was known to have had diabetes for three years and had gone into coma on three previous occasions. The present attack was precipitated by dietary indiscretions and began twenty-four hours previously with a sharp pain in the chest. She was in profound stupor; the deep reflexes could not be elicited, and her breathing was Kussmaul in character. Her blood sugar was 564 mg. and the carbon dioxide combining power of the blood 14.2 volumes per cent. She was given 1,500 cc. of 5 per cent dextrose intravenously and 220 units of insulin, but treatment was ineffective; her temperature steadily rose to 106.2, and she died in twelve hours, without recovering consciousness.

CASE 23.—A woman, aged 50, with a three years history of diabetes, went into coma four hours before admission. She was in deep stupor and in a profound state of shock, but breathing was not Kussmaul in character. The urine contained 8 per cent dextrose and moderate amounts of acetone. Her blood sugar was 600 mg. and the carbon dioxide combining power of her blood on two occasions was 43 and 51 volumes per cent. Because of the blood carbon dioxide figures, she was not treated with insulin and died in twelve hours in circulatory collapse.

CASE 24.—A youth, aged 18, with a two years history of diabetes, went into coma twenty-four hours before admission. He was in deep stupor, and breathing was Kussmaul in character. His blood sugar was 468 mg. and the carbon dioxide combining power of his blood 10 volumes per cent. He was given 2,000 cc. of saline solution, 100 Gm. of dextrose and 400 units of insulin in the eight hours he lived, but there was no response to treatment and his temperature rose to 105.2 before death.

CASE 25.—A man, aged 65, with a six weeks history of diabetes, had vomited for thirty-six hours and was admitted in profound coma and shock. He was markedly dehydrated, cold and cyanotic, and his pulse was barely perceptible. The urine contained 6 per cent dextrose and large quantities of acetone. His blood sugar was 540 mg. He was given 1,000 cc. of

5 per cent dextrose intravenously and 120 units of insulin. His blood sugar dropped to 296 mg., but he continued to vomit; his vasomotor collapse became more marked and he died in pulmonary edema five hours after admission.

CASE 26.—A woman, aged 37, with no previous history of diabetes, had lost weight for two months. She went into coma twelve hours before admission following an alcoholic debauch. She was in profound coma; the deep reflexes could not be elicited, and there was typical Kussmaul breathing. Her blood sugar was 470 mg., the carbon dioxide combining power of her blood 8 volumes per cent, and her leukocyte count 19,000. At the end of ten hours she had received 2,200 cc. of fluid intravenously, 240 Gm. of dextrose, and 180 units of insulin, but she remained in profound coma. Her temperature at this time was 101 and her blood pressure 120 systolic and 60 diastolic. At the end of eighteen hours, she had received 3,950 cc. of fluids and 275 units of insulin. The carbon dioxide had risen to 13 volumes per cent and she was still in deep coma. Her blood pressure was well maintained, but her temperature was steadily rising. At the end of twenty-two hours she had received 4,450 cc. of fluids and 335 units of insulin, but her temperature had risen to 105 and the carbon dioxide combining power of the blood was 10 volumes per cent. She died at the end of twenty-four hours. Culture of the blood taken two hours before death was negative. Autopsy revealed atrophy of the pancreas and chronic gastritis but no cause for the hyperpyrexia.

It is my purpose in presenting these protocols to analyze the causes of coma mortality in a general hospital. Thirty-three per cent of the deaths were associated with conditions fatal in themselves and were therefore unavoidable. In this group, coma is only of secondary importance and its control does not affect the outcome.

Nineteen cases were complicated by infections and of these ten were fatal. The mortality of diabetic coma associated with infections was therefore 52 per cent. Tuberculosis and pyogenic infections are of most serious consequence. Among the sixty-three uncomplicated cases, the mortality was only 22 per cent.

There is a tendency to assume that the problem of diabetic coma has been solved by the introduction of insulin and to attribute death in coma to mistreatment and negligence. I believe, however, that the protocols presented here confirm recent studies which indicate that there are factors of great importance other than the control of carbohydrate metabolism and the over-coming of ketosis by insulin, and that an appreciable coma mortality is inevitable in a general hospital even with adequate treatment. Examination of our protocols, for the purpose of analyzing the mechanism of death, reveals that the patients with diabetic coma died in one of two ways: either in vasomotor collapse (shock) or in a terminal hyperpyrexia. The so-called shock theory of diabetic coma has been the subject of intensive investigation in recent years. The factors involved have been studied by Atchley,¹ Peters² and their co-workers, and through their efforts the mechanism has been explained in part. Because of its importance in comprehending the problem of coma, I take the liberty of briefly summarizing their work.

M.; Eiseman, Anna J., and Hald, Pauline M.: The Nature of Diabetic Acidosis, *ibid.* 12: 377 (March) 1933.

The breakdown of carbohydrate metabolism causes a greatly increased water excretion and an equally pronounced excretion of electrolytes normally present in the intracellular and extracellular fluids, particularly sodium and potassium. With the onset of acidosis, the excretion of ketones greatly augments the loss of water and electrolytes. As a result of the rapid loss of water, sodium and potassium, there develops a depletion of base in the body sufficient to cause dehydration of tissues, the alkali deficit becomes more marked and hyperventilation ensues with its tendency to depress blood pressure. There develops, at the same time, an increased permeability of the capillary walls with the tendency of fluids to pass from the vessels into the tissue spaces. In mild forms the transudate is relatively free from proteins, but in severe grades of acidosis permeability is so altered that proteins pass with the fluids from the blood stream. The diminished blood volume, lowered blood pressure, capillary stasis and escape of fluids from the blood stream combine to produce the syndrome of shock.

During acidosis the blood is inspissated, as indicated by the normal or high serum protein and hemoglobin and the lowered blood volume. This depletion of plasma fluid is due not only to diuresis, vomiting and hyperventilation but also to loss of fluid through the capillary walls. Recovery in part involves the restoration of serum volume, but to a certain degree serum volume and body water act as independent variables and the replenishment of body fluids does not necessarily result in the restoration of blood volume. Circulatory failure, particularly peripheral stasis, is responsible for the escape of fluids from the circulatory system and for the failure to remain in or return to the vascular bed. Such circulatory failure can develop when carbohydrate metabolism is proceeding in a satisfactory manner and the serum carbon dioxide is rising. In the production of coma, ketosis and alkali deficit play an indirect rôle by producing diuresis and overventilation. If shock is an important factor, the restoration of blood volume becomes an essential aim of treatment and the blood protein figures as a measure of hemoconcentration and the blood pressure are as important as the blood sugar and the carbon dioxide of the blood in directing treatment.

Clinically, hemodilution seems to mark improvement. Delay in restoration of serum volume and hemoconcentration is associated with the continuance or increase of symptoms. Cases are cited in which the blood protein figures were a more accurate reflection of the clinical picture than either the blood sugar or the blood carbon dioxide. In one instance, cited by Peters,² the patient remained in profound coma with a carbon dioxide combining power of the blood well above the critical level. The liberal administration of fluid restored consciousness without significant change in the blood carbon dioxide or the blood sugar, but with a marked decrease of blood protein.

In twenty of our eighty-two patients the predominating clinical picture was that of vasomotor collapse or shock. Eight of these died. It is perhaps significant that the average age incidence of the eight with fatal issue was 49.1 years, in contrast to that of 32.5 years in the twelve that recovered. It is important to note that in only two of the eight fatal cases was there a failure of response to insulin as indicated by acetone excretion, blood sugar or carbon dioxide combining power of the blood. In case 13, the blood carbon dioxide rose from

10 volumes per cent to 31.4 volumes per cent in nine hours, and the blood sugar dropped from 580 to 380 mg. The patient remained comatose in spite of this improvement and died three hours later in circulatory collapse. Patient 16 remained in deep coma and died in shock twelve hours after admission, although acetone had disappeared from the urine and the blood sugar had dropped from 500 to 90 mg. Patient 12 remained in coma with a blood sugar of 120 mg. after acetone had disappeared from the urine. The blood pressure fell from 134 systolic and 84 diastolic to 84 systolic and 20 diastolic and the patient died in shock. Patient 18 was well out of coma. The blood sugar had dropped from 600 mg. to 100 mg. and the carbon dioxide combining power of the blood had risen from 21 to 41.6 volumes per cent, when on the third day the patient suddenly went into circulatory collapse and died in four hours. Patient 2 remained in coma and died in vasomotor collapse in spite of blood carbon dioxide readings of 43 and 51 volumes per cent. Patient 25 continued to vomit and died in circulatory collapse five hours after admission, although the blood sugar had dropped from 540 to 296 mg.

The importance of the circulatory aspects of coma and their independence of carbohydrate metabolism is strikingly illustrated by the following case:

CASE 27.—A girl, aged 17 years, had been treated at home for several days with dextrose, orange juice and insulin. On admission she was markedly dehydrated and comatose. She could not be aroused and the deep reflexes could not be elicited. She was in profound shock, her pulse was barely perceptible and only a few cubic centimeters of urine could be obtained by catheter, which contained 0.6 per cent sugar and a trace of acetone. Her blood sugar was 125 mg., the carbon dioxide combining power of the blood 33 volumes per cent and her blood urea 38 mg. Her condition remained critical for twelve hours. She was then placed on a continuous intravenous drip of 5 per cent dextrose in physiologic solution of sodium chloride, averaging 2,000 cc. in twenty-four hours. With the establishment of diuresis, she regained consciousness and made a rapid and complete recovery, although her blood carbon dioxide was still only 32 volumes per cent after the disappearance of all her symptoms.

There would appear to be a definite indication for the intravenous administration of fluids in this group because of the discrepancy that may exist between blood volume and body fluids. However, four of the patients who died were so treated; patient 16 received 1,200 cc. of 5 per cent dextrose in physiologic solution of sodium chloride intravenously in ten hours; patient 13 received 500 cc. of physiologic solution of sodium chloride intravenously in addition to 1,400 cc. by rectum in twelve hours; patient 12 received 2,100 cc. of 5 per cent dextrose in saline solution by continuous intravenous drip in twelve hours; patient 15 received 1,000 cc. of 5 per cent dextrose in saline solution by intravenous drip and 800 cc. by rectum in nine hours. It may be said that in three of these cases the amount of fluid administered by vein was inadequate, yet one has the distinct impression that the permeability of the capillaries had been so altered that it was impossible for fluids to be retained in the vascular bed. When this stage was reached, restoration of carbohydrate metabolism and elimination of ketosis no longer sufficed to bring about recovery. The degree of dehydration in this group appears to be more unfavorable prognostically than either the degree or the duration of coma. With advancing years, the outcome of dehydration and shock is particularly unfavorable.

The immediate cause of death in the remaining cases of true coma was hyperpyrexia. In these cases the clinical condition fails to respond to treatment. As the temperature rises the insulin is without effect and the patient dies without regaining consciousness. Occasionally a different picture is observed: Patient 17, as a result of vigorous treatment, had been aroused from profound coma. At the end of nine hours he had completely recovered consciousness, the urine contained only traces of sugar and acetone and the temperature was 97.4. One hour later the temperature began to rise and reached 106 before death. Autopsy revealed no cause for hyperpyrexia. Of the eleven cases in this group, five came to autopsy. Case 14 presented a terminal bronchopneumonia; case 11, a splenic tumor and evidence of sepsis. Cases 17, 1 and 26 at postmortem showed no cause for hyperpyrexia. In case 26 only was a blood culture made during the febrile period and in this instance it was negative. Of the cases not coming to autopsy only one, which has not been reported in detail, showed clinical evidence of bronchopneumonia. In none of the others were there clinical conditions to which the hyperpyrexia could be attributed.

To summarize, in this group of ten cases with hyperpyrexia there was definite evidence of bronchopneumonia in two patients and sepsis in one. In the remaining seven there was no cause for hyperpyrexia established either clinically or pathologically. There is the possibility of a terminal blood stream invasion, and blood culture studies are necessary to eliminate this as an etiologic factor. The negative blood culture in the one case so studied suggests that hyperpyrexia may be an essential part of the clinical picture either as a concomitant of dehydration or as a condition analogous to the leukocytosis encountered in acidosis. Prognostically, the development of an unexplained hyperpyrexia in diabetic coma has been of fatal significance, for none of our patients presenting this clinical feature have recovered and in its presence insulin is without effect.

SUMMARY

Vital statistics for New York City show that the steadily rising death rate for diabetes has not been checked by the introduction of insulin. This increasing mortality is a still unsolved problem in which the increased incidence of diabetes and the associated vascular disease probably play major rôles. I have, therefore, undertaken an analysis of the cases of diabetic coma occurring in adults during the insulin period for the purpose of investigating this phase of the problem.

In the insulin period 1923-1933, eighty-two cases of diabetic coma were treated in the adult wards of the Mount Sinai Hospital. There have been twenty-four deaths, a mortality of 29 per cent. Two patients died in the early months of 1923 before an adequate supply of insulin was available. There were only ten fatal cases of uncomplicated diabetic coma. Eight cases were associated with conditions fatal in themselves. In this group, coma was of only secondary importance and its control had no effect on the outcome.

The age incidence is of the utmost importance. This group does not include children under 14 years of age, yet the mortality of the forty-nine patients under 40 years is 12 per cent in contrast to that of 54 per cent in the thirty-three patients over this age. I believe that these figures are significant, particularly as the vital statistics of the city of New York show that the introduction of insulin has favorably affected the diabetic mortality only in the group under 35 years of age.

Two factors, shock and hyperpyrexia, are of importance in the mechanism of fatal diabetic coma. The vasomotor collapse or shock presents the problem of restoration of blood volume. In a certain number of elderly individuals, the circulatory collapse may persist and death may result even after carbohydrate metabolism is proceeding normally and the ketosis has been overcome. In this particular group, insulin does not prevent a fatal issue and there is unavoidable mortality despite adequate treatment with insulin and fluids.

In those who died of hyperpyrexia, the etiologic factor was determined only three times. There is the possibility that one is dealing, in the remaining seven cases, with a terminal blood invasion, but in view of the negative blood culture in the case cited, this phenomenon, when it occurs, must be regarded as an essential part of diabetic coma, perhaps as a concomitant of dehydration. This type of hyperpyrexia may be of cerebral origin. In our experience, insulin has proved ineffective in the presence of hyperpyrexia. This is an added source of unavoidable mortality.

ROENTGENOGRAPHIC VISUALIZATION OF SUBPERIOSTEAL HEMORRHAGE IN INFANTILE SCURVY

WALDO E. NELSON, M.D.
WILLIAM M. DOUGHTY, M.D.
AND
A. GRAEME MITCHELL, M.D.
CINCINNATI

The criteria for the roentgenographic diagnosis of infantile scurvy have been adequately established and described by Fraenkel,¹ Hess,² Wimberger,³ Pelkan,⁴ McLean and McIntosh,⁵ Bromer,⁶ Kato⁷ and others. These authors have demonstrated that such scorbutic changes in the bones as increased density at the end of the diaphysis, increased density around the epiphyseal centers (rimming of the nucleus of ossification in the epiphysis), ground-glass appearance of the shaft of the diaphysis and of the body of the epiphysis, thinning of the cortex of the diaphysis, lateral spurs at the end of the diaphysis, and epiphyseal separation (separation of the metaphysis) can usually be seen on the roentgenogram before the occurrence of subperiosteal hemorrhage. Kato believes that the last mentioned is the one sign that is absolutely unique in infantile scurvy. While not, therefore, an early or even a necessary sign of scurvy, subperiosteal hemorrhage is more characteristic than any other.

Certain features of the roentgenographic appearance of this condition are, perhaps, not widely appreciated. Hess states that the inner surface of the periosteum in subperiosteal hemorrhage is frequently lined with newly formed bone which, in the course of healing, becomes heavier and is readily observed in roentgenograms.

This periostitis ossificans may result in the clot being surrounded by a perfect shell of bone, with bony col-

Fig. 1.—Condition in case 2, Dec. 1, 1932: increased zones of density at the ends of the diaphyses with distinctly lessened density in the adjacent portion of the diaphyses; increased densities of the periphery of the epiphyseal centers; ground-glass appearance of the shafts; and lateral spurs extending from the proximal ends of the tibias and the distal ends of the femurs; epiphyseal separation at the distal end of the femur and the proximal end of the tibia (seen in lateral view). There is no evidence of subperiosteal hemorrhage.

Fig. 2.—Condition in case 2, Dec. 12, 1932, after eleven days of treatment: calcification of subperiosteal hemorrhages.

umns penetrating the deeper layers. Kato points out that, as healing takes place, the hematoma gradually

becomes organized and calcification sets in. McLean and McIntosh note that neither the elevated periosteum nor the hemorrhage may be discoverable in the roentgenogram until healing begins and calcium is deposited. In fact, these authors assert that, if there is evidence of calcification of the detached periosteum or the hematoma, it may be assumed that an antiscorbutic agent has been administered; Wimberger also believes this. While not specifically stressed by Howitt,⁸ she shows the serial roentgenograms of the bones in a scorbutic monkey which well demonstrate the increasing calcification that takes place in subperiosteal hemorrhages after the administration of orange juice.

We have been impressed by the fact that subperiosteal hemorrhage is frequently not diagnosed by the roentgenologist, although it may be suspected from physical examination. Unless serial roentgenograms are taken after treatment, we feel sure that the condition may be entirely overlooked. From the cases seen by us in the past two years we have selected several to

Fig. 3.—Condition in case 3, Jan. 10, 1933, after four days of treatment: increased zones of density at the ends of the diaphyses and about the epiphyseal centers; decreased zone of density in adjacent portion of diaphysis of the left femur with a lateral spur extending from this area; ground-glass appearance of the shafts but no evidence of subperiosteal hemorrhage.

illustrate the points under discussion. In none of these was there roentgenographic evidence of subperiosteal hemorrhage at the time of admission to the hospital.

CASE 1.—T. A., a boy, aged 8 months, white, admitted to the Children's Hospital, Sept. 3, 1930, because of "pain in the legs" of three weeks' duration, had been fed for several months on S. M. A. and had not received cod liver oil, orange juice or tomato juice. He was pale and irritable and cried when moved. There were hemorrhages into the gums, beading of the ribs, and tenderness over both femurs. The roentgenogram of the legs, taken the day after admission, did not demonstrate subperiosteal hemorrhage. The second roentgenogram, taken after the administration of orange juice for twenty days, showed marked calcification of the elevated periosteum at the lower end of each femur.

CASE 2.—P. K., a girl, aged 1 year, white, was admitted to the Children's Hospital, Dec. 1, 1932, with a history that for

8. Howitt, Beatrice F.: Spontaneous Scurvy in Monkeys, *Arch. Path.* 11:574 (April) 1931.

a month there had been pain when she was handled. Orange juice and tomato juice had been offered, but the child refused to take them. The diet had consisted entirely of pasteurized milk and soup. There was marked pallor and emaciation, bleeding into and from the gums, ledgelike beading of the ribs with depression of the sternum and the chondral portion of the ribs, and tenderness of the lower extremities. The diagnosis of scurvy was confirmed by the roentgenogram (fig. 1), but there was no evidence of subperiosteal hemorrhage at this time. Eleven days later, during which time orange juice had been given, marked calcification in the elevated periosteum was demonstrated on the roentgenogram (fig. 2).

CASE 3.—J. H., a girl, aged 9 months, white, admitted to the pediatric wards of the Cincinnati General Hospital, Jan. 5, 1933, had an infection of the upper respiratory tract. She had been fed on evaporated milk and had received cod liver oil but not orange juice. Her gums were swollen and had a purplish discoloration; there was beading of the ribs; the legs were held in a flexed position and there was tenderness of them on movement and pressure, but no swelling. A roentgenogram of the legs, taken five days after admission (fig. 3) (four days after

Fig. 4.—Condition in case 3, Jan. 17, 1933, after eleven days of treatment: calcification of small subperiosteal hemorrhage at the distal end of the left femur.

antiscorbutic treatment was instituted), did not show any evidence of subperiosteal hemorrhage. The picture taken eleven days after treatment was begun (fig. 4) showed a calcified periosteal elevation at the lower end of the left femur.

HEALING WITHOUT EVIDENCE OF SUBPERIOSTEAL HEMORRHAGE

Subperiosteal hemorrhage is not a necessary accompaniment of infantile scurvy. Healing may proceed without its occurrence. There may even be tenderness over the extremities without sufficient subperiosteal hemorrhage to be demonstrable on the roentgenogram. The following case is illustrative:

CASE 4.—D. W., a girl, aged 8½ months, white, admitted to the Children's Hospital, Nov. 1, 1931, had been extremely irritable for two weeks and cried out as if in pain when her legs were moved. Preceding this time there had been a period of two weeks during which she had had frequent stools. She had been fed on S. M. A. and had not received orange juice or cod liver oil, although apparently some tomato juice had been given occasionally. Ecchymotic spots were present on the gums, and there was pain on motion of the legs. A roentgenogram of the legs taken at the time of admission (fig. 5) showed

increased densities at the metaphyses and around the epiphyses, and a ground-glass appearance of the diaphyses and epiphyses. Reexamination twenty-three days later (fig. 6), during which time orange juice had been given, revealed no evidence of subperiosteal hemorrhage.

Fig. 5.—Condition in case 4, Nov. 2, 1931: increased densities at the ends of the diaphyses and around the epiphyseal centers; ground-glass appearance of the shafts.

Fig. 6.—Condition in case 4, Nov. 24, 1931, after twenty-three days of treatment: no evidence of subperiosteal hemorrhage.

COMMENT

The cases presented serve to emphasize the fact, previously noted but not sufficiently emphasized, that subperiosteal hemorrhages in infantile scurvy may not be visualized on the roentgenogram until calcium salts are

deposited in the periosteum. This deposition depends on the administration of vitamin C. When the roentgenogram demonstrates that calcium is present in the periosteum surrounding the hemorrhage, it indicates that vitamin C has been given and that healing is proceeding. Unless serial after the administration of of subperiosteal hemorrhage may be overlooked.

SYSTOLIC MURMURS IN CHILDREN

MURRAY H. BASS, M.D.

HERMAN MOND, M.D.

CHARLES R. MESSELOFF, M.D.

AND

ENID T. OPPENHEIMER, B.Sc.

NEW YORK

There are few differential diagnoses more difficult, and at the same time more important, than the differentiation between organic and functional murmurs. This question assumes a particular significance in childhood, when functional murmurs are common and when early rheumatic infection may give rise to faint systolic murmurs. In a given case the diagnosis of such soft blowing murmurs calls for most careful judgment, for the evaluation of the type of murmur is of extreme importance as regards the subsequent treatment of the child.

Various diagnostic criteria have been proposed to aid in distinguishing between organic and functional murmurs. Briefly stated, they are as follows:

Time in Cycle.—A functional murmur is almost invariably systolic, rarely diastolic, in time.

Quality.—Generally speaking, the functional murmur is very short and blowing. It rarely has the rough, rasping, or even musical qualities that are characteristic of organic murmurs.

Duration.—As a rule, the functional murmur is short and is heard only in the early part of systole.

Site of Maximum Intensity.—The functional murmur is usually best heard over the pulmonary area. Not infrequently, however, it is loudest over the apex and occasionally even over the aortic area.

Transmission of Murmur.—Distinct circumscribed localization is considered to be characteristic of a functional murmur. It is rarely heard beyond the precordial area.

Effect of Change of Position.—Occasionally a functional murmur may be elicited only when the patient is in the horizontal position, or a slight murmur may be accentuated by the recumbent posture.

Effect of Respiration.—A functional murmur may vary with the respiratory movements. As a rule, such a murmur is louder at the end of inspiration.

Effect of Exercise.—Exercise may accentuate, diminish or even abolish a functional murmur. Extreme variability is characteristic of functional murmurs.

Associated Pathologic Conditions.—Clinically and roentgenographically, the heart is normal in size and position. The absence of electrocardiographic changes

and of any other evidence of heart disease is an important diagnostic aid in determining whether a murmur is functional.

That these differential criteria are far from satisfactory when the physician is confronted with a specific case is a common experience. Frequently it is entirely impossible to make a positive diagnosis from a single physical examination. If during a shorter or longer period of observation systemic changes indicating organic disease, such as fever or joint pains, remain absent, the condition is more likely to be a functional one.

The differential diagnosis being frequently so difficult, it seemed worth while to obtain data by making objective records by means of the phonocardiograph. We were anxious to know whether the different types of murmurs might not show characteristic changes in the phonocardiogram. Moreover, it was realized that the record of the murmur thus graphically preserved was a permanent one and that it could be compared with records of other murmurs or with subsequent records of the same murmur.

We therefore decided to make heart sound tracings of a group of children with systolic murmurs of both the clinically organic and functional type, paying particular attention to the vibration frequency of the tracings obtained in these two types of case.

This paper is a report of our observations. While the number of cases studied was not sufficient for us to reach final conclusions, the results are unquestionably suggestive and are of sufficient interest to warrant a report.

PROCEDURE AND METHOD

The routine examination established for these cases was as follows: A complete and detailed history, with particular emphasis on the various rheumatic infections, was obtained in each case. The child was given a thorough examination. This included a search for foci of infection and evidence of rheumatic disease, and a complete study of the cardiovascular system, including a minute description of the type of murmur heard, measurement of the blood pressure, and a fluoroscopic examination of the heart for possible evidence of enlargement. In addition a complete blood count was done on each child, and the urine was examined. On the basis of these data a clinical diagnosis of either a functional or an organic murmur was made. The sound tracing was then taken. Whenever possible, the child was reexamined, both clinically and phonocardiographically.

The sound tracings were obtained by means of an electrical stethoscope.¹ The instrument consisted essentially of a three stage amplifier shielded in a metal case and regulated by a potentiometer. A series of electric filters allows the exclusion of frequencies below 130 cycles per second, and those above 300, 500 and 1,100 cycles per second. (For our purposes, frequencies above 1,100 cycles per second were excluded throughout.) A simple electromagnetic detector was fixed in position on the patient's chest with adhesive strips. In

1. The method used was first described by Prof. H. B. Williams, and the instrument was developed at the Bell Telephone Laboratories by Frederick and Dodge, in collaboration with Drs. Cabot, Gamble and Williams. A description of the method is to be found in the following articles:

Frederick, H. A., and Dodge, H. F.: The Stethophone: An Electrical Stethoscope, Bell System Tech. J. 3: 531-549 (Oct.) 1924.

Williams, H. B., and Dodge, H. F.: Analysis of Heart Sounds, Arch. Int. Med. 38: 683-693 (Dec.) 1924.

Williams, H. B.: New Method for Graphic Study of Heart Murmurs, Proc. Soc. Exper. Biol. & Med. 15: 179-181, 1920-1921.

This work was aided by the L. S. Frankenhimer Fund for Research in Pediatrics.

From the Pediatric Department and the Cardiographic Laboratory of the Mount Sinai Hospital.

order to obtain a graphic record, this apparatus was connected with one of the strings of a two-string Einthoven galvanometer, the second string being used for a simultaneous record of the electrocardiogram, lead III being generally used. In this way, correct timing of the sounds and murmurs in relation to the other events of the cardiac cycle could be obtained. The time was recorded by a tuning fork registering, by means of a phonic wheel, 0.02 second. The velocity of the moving film was so arranged that the space between two time ordinates amounted to 1 mm. This is twice the usual speed of the film in most of the galvanometers used for routine electrocardiography.

Fig. 1 (O. K.).—Normal case. No murmur is demonstrable on the curve.

Two curves were taken on each patient: 1. A tracing was made without the use of special filters (except the filter used permanently to exclude frequencies above 1,100 per second), the amplification being so arranged that the waves corresponding to the first heart sound gave deflections of from 15 to 30 mm. These curves usually showed only low frequency vibrations, the higher frequencies being demonstrable only at a much greater magnification. 2. A second tracing was therefore necessary in order to make the latter appear on the curve. Electric filters were here employed to exclude all vibration frequencies below 130 cycles per second, and the remaining higher frequencies, from 130 to 1,100 cycles per second, were recorded with much greater amplification. The expression "high" and "low" frequency vibrations, as used throughout this paper, denote respectively vibrations above or below the limiting frequency of 130 cycles per second.

SOME FEATURES OF SYSTOLIC MURMURS

Before we attempt to analyze and interpret our observations, a few remarks on the possible pathogenesis of both types of murmur may be in place. The terms "organic" and "functional" serve primarily only a practical clinical purpose. On the other hand, for the analysis of sound curves only such a classification as is founded on dynamic principles can be regarded as satisfactory. It is clear that the different systolic murmurs occurring in the various organic diseases are necessarily caused by different mechanisms. The systolic adventitious sounds heard in a pericarditis, in an aortic stenosis, in a coronary thrombosis or in a rheumatic mitral insufficiency are evidently dissimilar in origin. It seems better, therefore, to consider for the present one clear-cut type of organic murmur which is dynamically well defined, and which occurs most frequently; viz., the murmur due to changes in the mitral valves.

In the specific problem we are dealing with, the question that most frequently arises is: Has this particular child an organic mitral insufficiency due to rheumatic changes in the valves, or is the murmur due to those ill defined turbulences which may occur in any reservoir through which a liquid streams with varying velocity? To the latter group, the dynamics of which are still unknown, belong the functional systolic murmurs.

Systolic murmurs are composed of a mixture of vibration frequencies which may vary from 60 to 600 oscillations per second. As intimated, the higher vibration components are visible only in those curves that are recorded with high amplification and with filters excluding all vibrations of a frequency below 130 cycles per second. The two sets of curves taken in each case show clearly the composition of the murmurs with respect to vibration components above and below the frequency of 130 cycles per second.

The low frequency components of the murmurs, if present, are of the same approximate range as the heart sounds, from which they are rarely distinctly separable.

Usually the greater amplitude of the vibrations distinguishes the sound from the murmur, but the transition from the one to the other is, as a rule, so gradual that it is impossible to state exactly when the sound ends and the murmur begins. This is quite comprehensible when the fact is considered that there may be no essential difference in vibration frequency between the two. The acoustic impression that distinguishes sound from murmur must be due entirely to the few vibrations of great intensity and amplitude that give the sound its characteristic abruptness.

OBSERVATIONS AND CLINICAL CORRELATIONS

All systolic murmurs that we have recorded contained components of high vibration frequencies. These were present in all types of murmurs, organic and functional, with varying intensity. They occupied either the whole systole from the first to the second sound with which they merged, or only a part of the systolic period. The admixture of low vibrations, however, was quite variable. An analysis of our cases, as given

Fig. 2 (C. D.).—Clinically mitral insufficiency, beginning mitral stenosis and aortic insufficiency. After loud first sound a rough systolic murmur is heard at the apex and a fine diastolic murmur to the left of the sternum. Curves were taken from the apex. Both low and high pitched components were present. Higher pitched vibrations occupy the major part of systole. The lower components are irregularly distributed.

in the accompanying table, shows that components of low frequency were present in the majority (75 per cent) of cases with manifest organic heart disease, while they were absent in the great majority (86 per cent) of those with clinically normal hearts.

In all, sixty-four children with heart murmurs were studied. Of these, twenty-six had murmurs diagnosed

as organic by the usual and accepted clinical standards. Phonocardiographically, nineteen of these organic murmurs showed both low and high pitched vibrations. Of the remainder, six children had murmurs consisting exclusively of high pitched components. In one case the tracing was unsatisfactory.

A study of nine of the twenty-six organic systolic murmurs is particularly interesting. These nine murmurs were heard in children with chronic rheumatic cardiovalvular disease who presented a diastolic mur-

Fig. 3 (A. S.).—Systolic and diastolic murmur heard over the precordium. On the tracing, both high and low pitched vibrations occupy the entire systole. Diastolic murmur is less intense and gradually fades in diastole.

mur in addition to the systolic. There could therefore be no question of the organic nature of these nine systolic murmurs. We deem it highly significant that the sound tracings of the latter group showed consistently both low and high pitched components. We have, as

Analysis of Vibrations in Sixty-Four Cases

| Clinical Diagnosis | Total Number of Cases | High Pitched Vibrations Only | High and Low Pitched Vibrations | Tracings Indefinite |
|--------------------|-----------------------|------------------------------|---------------------------------|---------------------|
| Organic..... | 26 | 6 | 19 | 1 |
| Functional..... | 36 | 30 | 5 | 1 |
| Not diagnosed..... | 2 | .. | .. | 2 |

yet, seen no instance of an indisputable organic systolic murmur yielding a sound tracing without any low vibrations.

As has been stated, phonocardiograms obtained from six cases of supposed organic systolic murmurs showed only high frequency components and hence suggested a functional or nonorganic basis. The accuracy of the phonocardiographic interpretations, as contrasted with the clinical, is confirmed by a study of the history of one of these children:

S. L., a girl, aged 11 years, had had an occasional sore throat prior to tonsillectomy at the age of 3 years and scarlet fever complicated by an otitis media at 7 years. There were no cardiac symptoms. The patient was well developed without any evidence of rheumatic infection. There was a loud rough systolic murmur, lasting throughout systole, heard with maximum intensity in the third left interspace and transmitted upward to the vessels of the neck. Change of position from the sitting to the lying posture, as well as moderate exertion, caused an accentuation of the murmur. The blood pressure in the right arm in the recumbent position was 110 systolic and 54 diastolic. Fluoroscopic and roentgenographic examination of the heart revealed a prominence in the region of the pulmonary artery and left auricle, a suggestion of slight enlargement of the left ventricle and a prominent right auricle. The total transverse diameter of the heart was 10 cm. Urine and blood examinations were negative.

On the basis of these observations a diagnosis of congenital heart disease was made. Much to our surprise, the sound

tracing showed a high pitched systolic murmur, without low pitched vibrations, corresponding to the functional cases. Three months later, however, the child was reexamined, and no murmur was heard in any position, even after exercise.

The group of thirty-six murmurs diagnosed clinically as functional is more difficult to analyze. As indicated in the early part of this paper, one can never be absolutely certain that what is interpreted to be a functional murmur may not actually be an evidence of early organic heart disease. There is no murmur that can be designated as functional in the same unequivocal manner in which an organic systolic murmur can be diagnosed that is associated with a diastolic murmur.

In thirty of these thirty-six cases, the sound tracings were found to consist exclusively of high pitched vibrations. Of the remaining six, one showed indefinite tracings, and the other five yielded both high and low pitched components. Clinically, the latter five cases did not differ in any respect from the other thirty functional murmurs. Nevertheless, it is possible that they may have been early organic systolic blowing murmurs indistinguishable by the human ear. However, the fact that 86 per cent of the clinically functional murmurs yielded identical tracings, with high pitched vibrations only, suggests that this is a characteristic finding in functional murmurs.

In two additional cases it was impossible, either clinically or phonocardiographically, to decide on a reasonable differential diagnosis. The tracings of these cases were therefore classed as indefinite. The phonocardiograms exhibited mainly high frequency vibrations with a very slight admixture of low frequency components. Whether further tracings would have settled the question we do not know, since we had no opportunity to repeat the observations in these instances. In a few cases of similar nature in which reexamination was possible, the second phonocardiogram yielded a definite tracing susceptible of interpretation.

MECHANISM

It is clear that these differences in the curves may serve as an additional differential diagnostic criterion between functional and organic cases. The question, however, arises as to the cause of this prominent admixture of low vibrations in the organic cases. Several factors must be considered.

Fig. 4 (L. E.).—Functional systolic murmur heard to the left of the upper part of the sternum. Records taken from this point show only high pitched vibrations, which occupy about the first half of ventricular systole.

In the valvular organic murmurs, the murmur originates at the site of the valvular apparatus. Thus, in mitral insufficiency the high ventricular pressure forces a stream of blood back into the auricle through a more or less narrow opening caused by a shortening of the valvular leaves and their consequent inability to close tightly. The intensity of the murmur, therefore, will depend on the velocity, the pressure and the volume of the backflow, which plays on the free edge of the valve

as a bow on the strings of a violin. From this point, the vibrations are communicated to the whole system of auricle and ventricle.

Similar considerations are applicable to the case of aortic stenosis when a high pressure stream strikes against a narrowed aortic ring during ventricular systole. These organic murmurs, therefore, are usually louder than the functional type, which often appear as soft blows. This in itself is undoubtedly a factor that accounts in part for the low pitched vibrations.

We are justified in assuming that the louder the murmur the wider will be the area indirectly set into vibration and the greater the mass of tissue affected.

Fig. 5.—Functional systolic murmur at the pulmonic area, with reduplicated second sound. Tracings show high pitched components occupying the major portion of ventricular systole. Low vibration components are not demonstrable. The reduplicated second sound is probably the physiologic third heart sound.

Living tissues are at best not ideal conductors, and the original murmur is distorted by an admixture of widely varying vibrations. That this factor cannot, however, be solely responsible for the presence of low vibrations in organic murmurs is evident from the fact that components of low frequency are demonstrable even in rather soft organic murmurs and, on the other hand, may be lacking in those occasionally quite loud systolic murmurs at the pulmonic area which are universally regarded as functional.

Some additional factor, therefore, besides the intensity of the murmur must be assumed to account for the presence of low pitched vibrations in organic valvular cases. Our hypothesis is that, in the case of valvular lesions, the volume of blood set in direct vibration together with surrounding portions of the wall of the heart is relatively large and therefore gives ample occasion for the production of vibrations of low frequency, some of which may even lie below the acoustic range. This assumption follows easily from the previously described mechanism of the murmurs. On the other hand, it yields a hint as to the possible explanation of the nonvalvular or functional murmurs, which usually lack vibrations of low range.

We believe that the latter murmurs may be caused by purely local disturbances due to turbulences which set up vibrations of only a limited area of heart muscle, in the immediate vicinity of the whorl. If this is so, it would explain why the functional murmurs should consist mainly of high frequency vibrations.

SUMMARY

Sixty-four children with systolic murmurs, both organic and functional, were studied clinically and phonocardiographically. The records of all the murmurs contained vibrations of high frequency. Eighty-six per cent of the functional cases presented high pitched vibrations only, while organic cases revealed low as well as high pitched vibrations. This suggests an additional means of differentiating between the two types of murmurs.

ULCUS ACIDUM OF MECKEL'S DIVERTICULUM

LESTER R. DRAGSTEDT, M.D., PH.D.

CHICAGO

My purpose in this communication is to describe a case of perforating ulcer of the ileum near the entrance of a Meckel's diverticulum. It is of interest because of the support it affords to the view that the principal etiologic agent in gastric and duodenal ulcer is the corrosive action of the gastric juice and because of the light it throws on the question of the mechanism of ulcer pain.

The lesion is relatively rare if one may judge from the few cases collected in the recent reviews of Aschner and Karelitz¹ and of Lindau and Wulff.² It is probable, however, that a great many other cases have occurred and have either not been recognized or not been reported in the literature. In the majority of reported cases in which an ulcer has been found in the ileum in the neighborhood of Meckel's diverticulum, a careful search has revealed the presence of heterotopic gastric mucosa of the fundus type in the diverticulum. In certain cases in which the vitelline duct has persisted as a fistula opening at the umbilicus, this heterotopic gastric mucosa has been found to secrete an acid fluid containing pepsin. The lesion has been commonly described as "peptic" ulcer of Meckel's diverticulum to emphasize the view that the chemical or digestant action of the gastric juice has been considered the major factor in its pathogenesis. I have used the term "acid" ulcer because in the light of certain recent unpublished experiments it has appeared that the free hydrochloric acid of the gastric juice is of far greater significance in the cause of ulcer than is the proteolytic ferment.

Fig. 1.—Section taken longitudinally through the diverticulum as it passed into the ileum. The lining of the diverticulum (D) is composed entirely of gastric mucosa of the fundic type. I represents the mucosa of the ileum. Reduced from a photomicrograph with a magnification of 10 diameters.

The present case is unusual because the disease developed in a youth, aged 17, whereas most of the recorded cases have occurred in infancy and have caused an early death.

Read before the Chicago Pathological Society, Oct. 10, 1932.

From the Department of Surgery of the University of Chicago.

2. Lindau, Arvid, and Wulff, Helge: The Peptic Genesis of Gastric and Duodenal Ulcer, Especially in the Light of Ulcers in Meckel's Diverticulum and the Postoperative Ulcers in the Jejunum, *Surg., Gynec. & Obst.* 52: 621 (Nov.) 1931.

The following report contains the significant portions of the clinical history and observations:

J. W., a white youth, aged 17, came to the Albert Merritt Billings Memorial Hospital complaining of intermittent pain in the abdomen and marked muscular weakness. The pain was first noticed three years previous to admission and had become gradually more severe, and the attacks more frequent until the present time. It was described as a knifelike sticking sensation in the region of the umbilicus somewhat to the left of the midline. The history, checked by hospital observation, brought out the significant point that the pain was most apt to occur from one half to three quarters of an hour after the noon and evening meals. It was not relieved by food taking and slightly, if at all, by alkalis.

On physical examination the most significant finding was an extreme pallor, corroborated by blood examination, which revealed a profound secondary anemia. The red blood corpuscles numbered 3,400,000 per cubic millimeter and the hemoglobin was 60 per cent. No other abnormalities in the blood were found. The spleen was definitely enlarged and easily palpable. Chemical examination revealed the continuous presence of occult blood in the stools. A thorough laboratory and roentgenologic examination of the stomach, duodenum and colon revealed no abnormalities that might account for the bleeding.

Fig. 2.—Lining of the diverticulum showing gastric mucosa of the fundus type. Reduced from a photomicrograph with a magnification of 125 diameters.

Because of the enlarged spleen and the marked secondary anemia, a provisional diagnosis of early splenic anemia was made and an exploratory laparotomy decided on. In preparation for the operation, the patient was given two blood transfusions of 500 cc. of citrated blood each. Following the second transfusion, the patient suddenly developed symptoms suggesting an internal hemorrhage and shortly thereafter passed a copious stool containing a large amount of liquid and clotted blood. This gross hemorrhage of relatively unchanged blood, together with the symptoms of pain, seemed more compatible with a diagnosis of an ulcerated lesion in the lower small intestine or in the cecum, although the cause of the enlarged spleen remained undetermined.

At operation the spleen was found to be approximately three times its normal size, soft in consistency, and smooth. An inflammatory mass was found in the ileum about 40 cm. from the cecum. A section of ileum, approximately 60 cm. in length, containing this mass was resected and the continuity of the intestine reestablished by a lateral anastomosis between the proximal and the distal ileum. The patient made an uneventful recovery and when examined three months after operation presented a normal blood picture. The spleen was no longer palpable.

The portion of ileum resected was found to contain a Meckel's diverticulum about 4 cm. in length and completely surrounded by an inflammatory mass. Near the entrance of the diverticulum in the ileum was a round perforating ulcer approximately 1.5 cm. in diameter, unquestionably the source of the bleeding.

Histologic examination revealed that the entire lining of the diverticulum resembled very closely the mucosa of the normal stomach and in particular that characteristic of the fundus (figs. 1 and 2). A section taken through the ulcer (fig. 3) showed that it had penetrated the mucosa, submucosa and muscularis and had produced a marked inflammatory reaction in

Fig. 3.—Section through the ulcer in the ileum near the entrance of Meckel's diverticulum. It has penetrated through the muscularis and has produced an inflammatory reaction in the serosa. Reduced from a photomicrograph with a magnification of 20 diameters.

the serosa. The resulting adhesions had no doubt prevented a peritonitis. The absence of round cell infiltration in the submucosa and muscularis of the ileum a short distance from the ulcer (fig. 4) is interesting in view of the observations of Konjetzny and others on the occurrence of gastritis in cases of gastric ulcer.

The relation of pain to food taking in this case may probably be explained on the assumption that the cause of the pain is the irritation of the sensory nerve fibers in the ulcer by the acid gastric juice secreted in the

Fig. 4.—Section through the ileum about 6 cm. proximal to the ulcer. There is little or no evidence of inflammation in the submucosa or muscularis. Reduced from a photomicrograph with a magnification of 60 diameters.

diverticulum and poured out in the ileum. It was demonstrated some time ago by Ivy and Farrell³ that small pouches of the fundic portion of the stomach transplanted subcutaneously in dogs would secrete acid following a meal, presumably as a result of stimulation by some humoral agent. It is likely in this patient that in a similar way the ingestion of food was followed

after an appropriate interval by the secretion of gastric juice in the diverticulum. The failure of alkalis or food to relieve the pain so induced may be reasonably explained on their inability to reach the lower ileum and so neutralize the irritant acid.

OSTEOPETROSIS

REPORT OF CASE

O. B. MAYER, M.D.

AND

T. A. PITTS, M.D.

COLUMBIA, S. C.

Osteopetrosis is commonly spoken of as "marble bones"; recently it was referred to as "chalky bones."¹ The condition was first described by Albers-Schönberg² in 1904, and it is usually referred to by his name. Reviews of cases may be found in articles by Karshner,³ Davis,⁴ and Alexander.⁵ Pirie,¹ in 1930, reported a total of twenty-six cases in the literature and added five. Seventeen additional cases have appeared,⁶ making a grand total of forty-eight. Few cases have lent themselves to thorough investigation; only a small number have come to autopsy and none have shown a definite etiology.

The present case report is offered because of its rarity, the relatively long observation, and its unusual features. It has been as completely studied as circumstances permitted.

History.—A white girl, born, July 6, 1915, was in good health, March 27, 1926, when a spontaneous fracture of the right femur occurred. A roentgenogram demonstrated the fracture and the presence of marble bones (fig. 1).

The parents were maternal first cousins. The past history is otherwise irrelevant. There was an older normal sister and brother. Intervening were three uninduced miscarriages and a stillbirth. This case thus represents the last of seven pregnancies.

During the latter months of gestation, the mother was ill with malaria and subsisted largely on sweet milk. Her condition reached such a state that induced labor was considered, but she went to term. The baby was entirely breast fed for the first year, and then whole cow's milk, cereals, eggs and

meats were gradually added and, occasionally, oranges. Later carbohydrates were given in excess. No cod liver oil was taken. Head rolling developed when the child was 1 year old. No illness of consequence occurred during infancy. The mother suspected blindness when the child was 6 months of age. Development and growth were normal. Slight deafness was noted only two weeks before we examined her. She was of a happy disposition and bright mentally. She never attended school but liked music and played and sang by ear. Owing to blindness she was not permitted outdoors until early childhood and had little exposure to the sun's rays.

Examination.—In May, 1926, the child showed adolescent changes, was pale, poorly nourished and poorly developed, and exhibited constant movement of the hands and head. The mouth resembled that of an elderly edentulous woman. The skin and hair were normal. The head had large temporal, parietal and vortex bossae but was not hydrocephalic. The teeth were out of line and carious. The gums were wide. The hard palate showed a deep longitudinal sulcus. The tonsils were small. The nose was normal. The eyes showed a persistent rolling and gross nystagmoid movement with alternating strabismus. The pupils were regular and reacted uncertainly to light. The fundi showed primary optic atrophy. The ears were normal. There was a chain of enlarged posterior and submaxillary glands. The sternum was prominent and the thorax had an increased anteroposterior diameter. There was no rosary. The lungs and heart were normal. The blood pressure was 130 systolic, 67 diastolic. The spleen was enlarged below the costal margin. The liver was not enlarged. There was moderate bilateral genu recurvatum. The deep reflexes and sensations were normal. The muscles were small but not atrophic. At the point of fracture there was slight pain on pressure; no callus was felt, no increased mobility and no deformity. The pulse rate was 80, the temperature 98, and respiration normal. Examination of the urine and stool gave negative results. The differential count was normal. Hemoglobin (Dare) was 70 per cent. The coagulation time was three and one-half minutes. Leukocytes numbered 6,200; erythrocytes, 3,100,000. A test for malaria gave negative results. The Wassermann reaction of the father and mother was negative. A phenolsulphonphthalein test intramuscularly showed the total dye excretion for two hours of 75 per cent. Permission was refused for withdrawal of blood. The patient left the hospital in May, 1926.

The roentgenographic observations in osteopetrosis are typical. The outstanding characteristics as described by Albers-Schönberg and others are a generalized increased radiopaqueness of all bones from the high calcium content. The general surface contour is not disturbed. This case demonstrates the classic changes as described in the literature and some additional ones (fig. 2). A description of them follows:

Roentgen Examination in 1926.—The skull was elongated and was smooth in outline. The frontoparietal sutures were ununited. The base, the posterior part of the parietal, and the upper part of the occipital bones showed proportionate increase in density. The mastoid areas were so dense that no cells were seen. The bones of the face, including the lower jaw, were small and dense. The lower jaw showed areas of density following somewhat the course of the neural canal. The teeth were poorly formed and were less dense than normal. Many were missing.

The vertebrae had asymmetrical, rounded edges. The central portion of the bodies was comparatively dense. The spinal canal was not encroached on. There was an irregular thin deposit parallel to the inferior surface of the vertebrae (fig. 3) and to a less degree along the superior surfaces. The intervertebral disks were uninvolved.

The sternum showed four distinct pieces, each with a marked increased density at the ends.

The hyoid, clavicles, scapula, ribs, sacrum, coccyx and patellas showed only the general bone disease.

The normal thin portion of the ilium remained relatively uninvolved. The junctions of the interior rami of the pubes and the ischium showed an enlargement.

The femurs showed the most marked change of the long bones. The medullary canals were extremely narrow, because of a central encroachment. The right femur immediately below the great trochanter showed a complete transverse fracture with ends approximated and a small amount of callus. The medial half had apparently fused.

The tibiae showed proximal and distal clubbing. The distal ends had transverse bands of alternating density about 0.5 cm.

Fig. 1.—Fracture of right femur; osteopetrosis.

wide. The fibulas showed little alteration. The feet shared in the general change. The proximal ends of the humeri were markedly clubbed. The lower ends, except immediately contiguous to the joint surfaces, were more normal.

The radii and ulnas showed clubbing at the distal ends, with corresponding transverse bands of density (fig. 2).

The carpals showed a uniform change, which was most marked at the joint surfaces.

The metacarpals from the second to the fifth showed relatively marked density at the distal ends, less marked at the proximal ends. The first metacarpal showed the opposite relation.

All phalanges had definite bands of density proximally. The distal ends of the first and second rows exhibited a cap-like density beneath the joint surfaces extending proximally for a short distance on the lateral aspect (fig. 2).

Second Hospitalization.—The patient reentered the hospital, Aug. 29, 1932, and remained until September 3. Five weeks after the seventeenth birthday, the first menstrual period appeared. Uterine bleeding continued, confining the patient to bed with weakness, nausea, vomiting, severe headache, general abdominal soreness, and fever as high as 102 F. Little food was retained. The bowels were constipated. She was seen and hospitalized twelve days after the onset of the illness.

A second spontaneous fracture of the right femur occurred during the year 1927. Her health otherwise was good.

Physical examination showed a general critical condition, marked secondary anemia, waxy-like appearance of the skin, further dental caries, enlargement of the spleen to the iliac crest, kyphosis of the lower thoracic spine, and 2.5 cm. shortening of the right lower extremity as the outstanding changes in the physical state since the former examination. She had developed in an otherwise normal manner. She was as well as formerly at this writing, in April, 1933.

The hemoglobin was 10 per cent (Dare). Erythrocytes numbered 820,000; leukocytes, 12,300; polymorphonuclears, 58 per cent; small mononuclears, 35 per cent, transitionals, 3 per cent; large mononuclears, 2 per cent; myelocytes, 2 per cent. The bleeding time was three and one-half minutes. A test for malaria was negative. Blood Wassermann and Kahn tests were negative. The blood serum calcium was 9.8 mg.; blood serum phosphorus, 4.4 mg. A blood smear showed marked secondary anemia. Examination of the urine was essentially negative. Examination of the stool was negative. The calcium in 400 cc. of urine collected from 11 a. m. to 5 p. m. was 5.04 mg. A transfusion of 450 cc. of whole blood was given. In three days the temperature was normal and a remarkable improvement was noted in appetite and strength. A small amount of uterine bleeding was present when the patient left the hospital, against advice, on the fourth day.

Roentgen examination in 1932 showed a marked increase in the density of all the bones.

The long bones showed more clubbing, but the distribution of the clubbing remained the same. The transverse bands of density in the long bones had been lost, giving way to the characteristic generalized density, proving the progressiveness of the condition. One of the most striking changes was at the costovertebral junction, which gave the appearance of healed fractures with excess callus formation (fig. 3). The femur showed more bowing at the site of the fracture, but no excess callus. The exact site of the fracture could not be identified.

The condition marble bones presents a definite picture clinically and roentgenologically. Minor variations occur rather frequently. Observers agree on an abnormal osseous calcium metabolism but cannot satisfactorily explain it. The rôle of parathyroid secretion and vitamins has not been established.

In our own case, the mother's illness before and after delivery, her diet largely restricted to milk, and the

Fig. 2. (May, 1926).—Corresponding transverse bands of radius and ulnar with distal clubbing. Proximal clubbing of humerus. Changes in carpals, metacarpals and phalanges.

long exclusion from ultraviolet rays suggest an adverse influence on the development and growth of the fetus, and alteration in the vitamins and mineral content of the breast milk. This, with an infant also deprived of the sun's rays during its first year, would favor the

production of bones of less dense or rarefied characteristics, but on the contrary the bones developed considerable density. Furthermore, no convulsions, tetany, or evidence of hypocalcemia were known to exist. Considered in the light of these facts, osteopetrosis is paradoxical in that dense bones have developed under conditions that ordinarily form bones of low calcium content.

Since 1930, almost as many cases have been reported as occurred in the entire preceding period. There is probably no increase in interfamilial marriage, and certainly prenatal dieting is more scientific generally. The cause of osteopetrosis is more remote. Nothing appears in the literature to disprove a congenital origin. Search fails to reveal a single case produced experimentally, either in man or in animals, even after the removal of the parathyroids. Recently Pirie¹ studied a family group of osteopetrosis and found, by roentgen changes

Fig. 3 (September, 1932).—Bone overgrowth at costovertebral articulation.

manifested by bands of increased density near the distal ends, especially in the long bones, signs of developing osteopetrosis in a child. His observations suggest that the condition may develop postnatally, but the case had a definite hereditary influence. The bones of the parents and the elder brother in our case were entirely normal roentgenographically. We feel that the hereditary influence is a very strong factor. Intermarriage has been constantly present.

Bulger and Barr,⁷ Jaffe,⁸ Camp⁹ and others have furnished interesting data proving that parathyroid secretion is a most important factor in the decalcification of bone; but no relation to marble bones has been proved. Flood⁶ studied calcium metabolism in a single case, finding a hypercalcemia and high calcium kidney

threshold. Parathyroid extract did not appreciably alter the calcium balance. Ballin¹⁰ demonstrates excellent results in the treatment of Paget's disease of the bone and allied conditions by parathyroidectomy.

In our case, the progressive nature of osteopetrosis has been manifested by a loss of the transverse bands, generally increased bone density, further encroachment on the medullary canals, advancing alveolar destruction and dental caries, and marked secondary anemia with a tremendous increase in the size of the spleen.

The crisis accompanying the delayed first menstrual period at the age of 17 years suggests an endocrine imbalance.

The parents of this patient were maternal first cousins. The condition was found incidentally on roentgen examination for the first spontaneous fracture of the right femur at the age of 11. The second fracture occurred one year later. Both healed without incident. The mother was desperately ill the last few months of gestation. Neither she nor the infant had exposure to the sun's rays for many months. No dietary cause nor kidney insufficiency was found. Secondary anemia, dental caries, optic atrophy, enlarged spleen, and the roentgenologic observations furnish a composite picture of osteopetrosis.

Medical Building.

PNEUMOCEPHALUS AND SUBARACHNOID HEMORRHAGE FOLLOWING SKULL FRACTURE

MOSES KESCHNER, M.D.

AND

JOSEPH LANDER, M.D.

NEW YORK

Pneumocephalus occurs in about 60 per cent of the cases of fracture of the skull involving the frontal sinus. The mechanism of the process whereby air reaches the cerebral ventricles or forms a cyst within the brain substance is generally accepted to be as follows: At the time of the fracture, there occurs, usually, a rupture of the adjacent meninges with secondary adhesions between the pia and the arachnoid. When, subsequently, the patient coughs, sneezes, strains or swallows, increased pressure in the sinus results, and air is forced through the fracture and the torn adjacent meninges into the brain substance, where it is trapped by the valvelike action of the meninges. As more and more air thus accumulates intracerebrally, the cyst gradually approaches the ventricle, into which, finally, the air escapes. In some cases the air is not intraventricular but remains encysted in the brain substance. Another theoretical method by which air might reach the ventricles is, of course, through the subarachnoid space, and the foramina of Luschka and Magendie.

The finding of bloody spinal fluid in such cases is not uncommon and is, of course, due to laceration of the meninges and brain.

The following case of traumatic pneumocephalus with bloody spinal fluid has come recently under our observation:

J. J., a man, aged 27, a pantryman at the Montefiore Hospital, was found lying unconscious in a street late on the

10. Ballin, Max: *Ann. Surg.* 96:649-665 (Oct.) 1932.
From the Neurological Service of Montefiore Hospital.

evening of Dec. 31, 1931, and was brought by ambulance to Bellevue Hospital. Here, examination showed contusions of the face. Lumbar puncture yielded a clear fluid under normal pressure. He was thought to be in alcoholic coma. He remained in this condition for about twelve hours. On regaining consciousness, he left the hospital "against advice." Although he felt dazed, he traveled alone a distance of about 12 miles in the subway to his quarters at the Montefiore Hospital. On arrival, he immediately went to bed and slept for four hours. He rose to take some nourishment and returned to bed and slept for twelve hours. On arising the next morn-

ing, about thirty-two hours after the accident, he drank a glass of water, which he promptly vomited. After waiting about half an hour, he went to the dining room for his breakfast, which he also vomited after ten minutes. He felt weak and returned to bed, where he stayed till about 2 p. m., when he awoke with a severe headache. He remained in this condition till the following morning, at which time he was admitted to the ward, complaining of headache, nausea, vomiting and pain between the eyes and at the root of the nose. Here he gave a history of having been struck by a taxicab on the evening of December 31, while intoxicated. Further details were not available. His previous, family and personal past histories are not relevant.

Examination revealed contusions and abrasions over the right forehead and the left eye and at the root of the nose; the blood pressure was 130 systolic, 85 diastolic; there was a slight rigidity of the neck; the left pupil was larger than the right; the margin of the left optic nerve head appeared somewhat "fuzzy"; there was a dull tympany on percussion over the left frontal area; weakness of the right grip; depressed deep reflexes in the lower extremities, and a bilateral Mendel-Bechterew sign.

Cisternal puncture, performed with the patient in the reclining posture on the side with the head flexed, yielded no fluid, but about 5 cc. of air was withdrawn by aspiration. Spinal puncture below the fourth lumbar vertebra was then performed and revealed a uniformly bloody fluid. Another puncture in the next higher interspace yielded a similar fluid. Following the second puncture, cisternal puncture was repeated; this time a bloody fluid, though of a lighter color than that obtained on lumbar puncture, was obtained.

Stereoscopic roentgen examination of the skull showed the presence of a large amount of air in the lateral and third ventricles (figs. 1 and 2), which appeared normal in size and not displaced. A moderate amount of air was also visualized in the subarachnoid space. There was a fracture involving the

left frontal sinus a little above the level of the left orbit. On Jan. 11, 1932, a roentgen examination of the skull showed that most of the air had disappeared, and on February 1 only a very small amount was left in the subarachnoid space.

The patient's course in the hospital was uneventful. He was kept at absolute rest, in bed, and was advised against blowing his nose.

At the time of his discharge from the hospital, February 3, neurologic examination showed nothing significant. Reexamination, June 10, revealed no abnormality.

COMMENT

It is noteworthy that lumbar puncture done at Bellevue Hospital several hours after the accident showed perfectly clear spinal fluid, while puncture done several days after the accident revealed a uniformly bloody fluid. If one assumes the existence of a true cerebrospinal fluid circulation, there should certainly have been blood in the spinal subarachnoid space several hours after the accident. If, however, one accepts the theory of Sachs, that substances in the cerebrospinal fluid spread by *diffusion*, rather than by true *circulation*, this question is no longer a difficult one to answer.

We are unable to explain why the bloody fluid obtained by lumbar puncture was darker than that obtained by cisternal puncture. In neither case was there any reason to suspect that the blood was due to puncture.

The literature contains reports of about ninety-five cases of pneumocephalus, the great majority of which were traumatic, the others being due to abscesses, spontaneous rupture of a tumor into the sinuses, and

Fig. 1.—Lateral view of skull showing lateral and third ventricles uniformly filled with air.

Fig. 2.—Anteroposterior view of skull showing fracture of left frontal sinus and uniformly dilated anterior horns with no displacement.

similar causes. More than half of these ninety-five patients recovered. Of the ninety-five cases, there are adequate data regarding the cerebrospinal fluid in less than thirty. In only fourteen of these cases was bloody cerebrospinal fluid definitely found that was not due to operative procedures. Eleven of these fourteen patients recovered.

SYMPATHECTOMY FOR INTRACTABLE PAIN IN INOPERABLE CANCER OF THE CERVIX

J. P. GREENHILL, M.D.

AND

H. E. SCHMITZ, M.D.

CHICAGO

The results obtained with radiation therapy in inoperable malignant growth are most unsatisfactory. In the majority of instances the doomed individual suffers from excruciating pain which necessitates the almost continuous use of narcotics. The pain is due to the extension of the growth to and about adjacent nerves. This is particularly true of malignant growths in the female genitalia, notably carcinoma of the cervix of the uterus. At present, only two satisfactory ways exist in which the constant suffering may be alleviated. Both are operative procedures. One, known as cordotomy, consists of section of the anterolateral columns of the spinal cord. The other, known as sympathectomy, consists, in cases of malignant growths of the pelvis, in removal of the so-called presacral nerve or superior hypogastric plexus.

Cordotomy will relieve pain, but it is an operation that should be carried out only by one skilled in neurologic surgery. The operation requires a laminectomy of the second, third, fourth and fifth thoracic spines and "unless the incision in the cord is accurately placed, the pain may not be completely relieved, or the motor pathways may be damaged, resulting in paralysis of the legs and interference with sphincter control."¹

Sympathectomy, on the other hand, is an operation that any gynecologist may readily perform. The risk involved is slight, the technic is not complicated, and local infiltration anesthesia may be used for a large part of and in some instances for the entire operation. Furthermore, since the abdomen must be opened to carry out this procedure, one is enabled to inspect and palpate the extent of the carcinomatous involvement.

The operation to be described is the one recommended by Cotte.² It consists of resection of the post-ganglionic fibers of the sympathetic nervous system which innervate the pelvic organs, including the uterus, bladder, anus and lower part of the ureter in women and the prostate and seminal vesicles in men. Cotte recommended the operation for a variety of conditions, chief among them being inoperable carcinoma of the uterus, dysmenorrhea, dyspareunia, vaginismus, painful cystitis, functional disturbances of the bladder, persistent leukorrhea, nymphomania, frigidity, pruritus vulvae, amenorrhea and trophic disturbances of the ovary. We believe this array of indications is far too generous because most of the conditions enumerated can be relieved without surgical intervention. We are, however, unequivocally convinced of the great usefulness of the operation in cases of unbearable pain associated with inoperable malignancy of the pelvis.

HISTORY

The first attempt to relieve pelvic pain by resecting nerves was made by Jaboulay³ in 1898, who inter-

rupted the afferent pathways in the sacral sympathetic chains. The next year, Ruggi⁴ advised resection of the utero-ovarian plexus, and in 1921 Leriche's⁵ report aroused new interest in this field of surgery. The latter recommended periarterial sympathectomy of the internal iliac arteries for the purpose of relieving dysmenorrhea and menstrual and trophic disturbances, although he performed the first periarterial sympathectomies in 1913. During the next few years, numerous publications appeared in French, Italian and Spanish

Fig. 1.—Origin of superior hypogastric plexus or presacral nerve (slightly modified from Henle).

journals. Because Leriche's operation was somewhat difficult to perform, Cotte, in 1925, recommended resection of the superior hypogastric plexus, which yielded the same results. The only American who reported doing this operation for carcinoma is Kordenat,⁶ who reported one case.

ANATOMY

Those interested in the minute details of the structures involved are referred to Cotte's two books and to the articles by Elaut⁷ and Fontaine and Herrmann.⁸ We shall here take up only the important points.

Read before the Chicago Gynecological Society, April 21, 1933.

The portion of nerve tissue that is resected in Cotte's operation is the *nervus sympathicus pelvici*. To it many names have been given, but that suggested by Latarjet and Bonnet,⁹ namely, *presacral nerve*, is the one in common use at the present time. However, the name *superior hypogastric plexus*, suggested by Hovelacque,¹⁰ is also frequently employed. The word *plexus* is preferable to the word *nerve* because in Elaut's series of fifty anatomic dissections the tissue excised was a single nerve in only twelve cases (24 per cent). In all the other instances it consisted of an intricate network of nerve fibers. Furthermore, as Elaut pointed out, the plexus is not *presacral* but *prelumbar*. Hence, the term "*presacral nerve*" is incorrect anatomically. Nevertheless, since it has been used extensively in the literature we shall use it interchangeably with *superior hypogastric plexus*.

The *presacral nerve* arises as follows (fig. 1): Two nerves course along the lateral margins of the anterior surface of the aorta from the origin of the superior mesenteric artery down to the origin of the inferior mesenteric artery. Between these two nerves, known as the *intermesenteric plexuses* or *nerves*, are a few anastomoses that traverse the aorta. The *intermesenteric nerves* are joined by branches from the lumbar sympathetic chain. As they descend, at the level of the origin of the inferior mesenteric artery they divide into two bundles. One, known as the *inferior mesenteric plexus*, follows the inferior mesenteric artery, and the other, known as the *superior hypogastric plexus* or *presacral nerve*, continues down the anterior wall of the aorta and below it. The *superior hypogastric plexus* varies considerably in appearance, but generally it is triangular with the base caudad and the apex pointing cephalad. At the base the plexus divides into two branches, known as the *right* and *left hypogastric nerves*. These are actual nerves and course medially to but not exactly parallel with the hypogastric arteries. They extend down into the pelvic cavity, where they expand on both sides of the pelvic organs and receive branches from the sacral plexus to form the *inferior hypogastric plexuses* of Hovelacque. According to Cotte, these hypogastric plexuses were erroneously called the *cervical ganglions* of the uterus by Lee and Frankenhauser. The plexuses consist of large ganglionic plates situated on each side of and behind the cervix just above the posterior fornix and in front of the rectum. They are the plexuses that supply branches to the uterus. The ovaries obtain their chief nerve supply from the ovarian plexuses, which arise from the *intermesenteric* and *renal plexuses* and follow the ovarian arteries down into the suspensory ligaments of the ovaries. In the suspensory ligament each ovarian plexus divides into an external tubular branch, which innervates the fallopian tube, and one or more internal branches, which enter the hilus of the ovary. The nerves that supply the vagina arise in the anterior part of the hypogastric plexus, the vesicovaginal branches of this plexus and the sacral roots. The nerves that supply the rectum, the bladder and the lower portions of the ureters have their origin in the *inferior hypogastric plexuses*.

TOPOGRAPHIC ANATOMY

The *presacral nerve* can readily be found if one looks for a triangle the base of which corresponds to a line uniting the two common iliac arteries at the

level of the sacral promontory, the sides being these arteries and the apex of the triangle being the point of bifurcation of the aorta (figs. 1 and 2). This triangle occupies the lower third of the fourth lumbar vertebra, the last intervertebral cartilaginous disk and the fifth lumbar vertebra. The base of the triangle is about 7 cm. in length and the distance from the base to the apex is almost 6 cm. A large part of the left side of the triangle is occupied by the left common iliac vein, which arises from the inferior vena cava and passes downward from beneath the right common iliac artery to accompany the left common iliac artery. The triangle is divided vertically into two equal halves by the middle sacral artery, which arises from the back part of the aorta just at its bifurcation and courses straight down to the upper part of the coccyx. Since this vessel is easily felt through the peritoneum it is often mistaken for the *presacral nerve*, which runs parallel to it. From the origin of the inferior mesenteric artery down to the bifurcation of the aorta, the nerve fibers lie on the aorta, separated from it only by a layer of thin connective tissue. The branches of

Fig. 2.—Field of operation and tissue containing *presacral nerve* and *hypogastric nerves*.

the plexus which accompany the left common iliac vein are separated from this vessel by areolar tissue, making elevation of the nerve easy. However, as the nerve fibers go still farther down, they lie on the peritoneum and perichondrium of the last lumbar vertebra, and the cartilaginous disk between this vertebra and the sacrum. At this point the plexus lies above the middle sacral artery and veins.

The entire triangle is covered with peritoneum; hence the nerve plexus lies between the peritoneum and the underlying bones. The fibers are not adherent to the peritoneum but are separated from it by more or less fatty tissue, depending on the obesity of the patient.

Usually the inferior mesenteric vessels may be seen to the left of the midline, but sometimes these vessels are in intimate contact with the *presacral nerve*. This is due to an abnormal anatomic position and undue length of the pelvic mesocolon, whereby the right root of it is inserted in the midline or still farther to the right. Hence, in these cases the incision in the posterior parietal peritoneum must be made to the right of the midline and the nerve can be reached only through

9. Latarjet, A., and Bonnet, P.: *Lyon chir.* 9: 619, 1913.

10. Hovelacque: *Anatomie des nerfs crâniens et rachidiens et du système grand sympathique*, Paris, Gaston Doin, 1927.

the thick mass at the base of the mesocolon. This is a difficult procedure.

In Elaut's fifty dissections he never found the presacral nerve in front of the sacrum. It was always above the promontory in front of the body of the fifth lumbar vertebra and the intervertebral cartilaginous disks below and above this vertebra. Hence the nerve was always prelumbar. Elaut found that the bifurcation of the nerve varies considerably. Usually it is at a point below the bifurcation of the aorta; occasionally it is at the same level as the division of the aorta, but rarely it is at the base of the triangle.

There is seldom any need to worry about the ureters except in the cases in which the pelvic mesocolon must be pulled to the left to permit exposure of the triangle. Only the right ureter must be considered, but since it

is firmly adherent to the peritoneum and the presacral nerve is not, it is easy to differentiate between the ureter and the nerve.

PHYSIOLOGY

Two questions may properly be raised. One is whether the large fibers of the sympathetic system are really sensory. Ranson says that proof of this was offered more than twenty-five years ago by Edgeworth and that he confirmed Edgeworth's observations. If the roots of the spinal nerves are cut proximal to the spinal ganglions, all the motor fibers degenerate but the sensory fibers remain.

The hypogastric plexus produces vasoconstriction of the blood vessels of the internal genital organs and it inhibits the secretion

of the genital glands, whereas the parasympathetic nerves produce the opposite effect. Section of the superior hypogastric plexus does not alter the normal menstrual cycle nor does it interfere with uterine contractions during labor. Likewise, section does not produce glandular atrophy or any disturbances in the motor function of the bladder or rectum. Therefore the nerve fibers of the superior hypogastric plexus are sensory and not motor. They carry the sensations from the internal genital organs to the medullary centers. Hence resection of the portion of the superior hypogastric plexus above the hypogastric ganglion is a simple way of relieving a patient of severe pain arising in the pelvic organs.

Fig. 3.—Excised piece of tissue measuring 10 cm. in length. Upper half of triangle contains presacral nerve and part of intermesenteric plexus. Lower half contains the two hypogastric nerves. Lateral projections just below middle are branches from fourth lumbar ganglions. Nerve fibers are clearly visible throughout entire piece of tissue.

The second question that may be raised concerns the possible harm done by removing a portion of the sympathetic nervous system. Ranson¹¹ states that Cannon and his students completely removed "the sympathetic chain on both sides, from the highest cervical to the lowest sacral ganglion. Such completely sympathectomized cats have lived under laboratory conditions for many months. . . . Everything indicates that almost any part of the sympathetic system can be removed without seriously endangering life."

INDICATIONS FOR RESECTION OF THE PRESACRAL NERVE

It is advisable to resect the superior hypogastric plexus in cases in which there is intractable pain in the lower part of the abdomen, the back and down the lower extremities associated with inoperable or recurrent carcinoma of the female reproductive organs, especially the cervix uteri. The pain in these cases is usually due to compression of the nerves in the parametrium and to inflammatory or specific involvement of these nerves. In some cases the operation will disclose a specific cause for the pain other than direct nerve involvement, such as an inflammatory mass. Resection of the presacral nerve is useless, however, if the pain is due to compression of sacral nerve roots, to pressure of involved glands on the obturator nerve or to distant metastases. Ferey¹² recommends the prophylactic resection of this nerve in all cases in which a hysterectomy is performed for carcinoma of the uterus.

TECHNIC OF OPERATION

Since many of the patients who should be subjected to this type of operation are poor surgical risks, it is best to open the abdomen under direct infiltration anesthesia. This is a very simple procedure and requires only a few minutes. The rest of the operation may readily be performed under a short ethylene or ether anesthesia or even under infiltration anesthesia. The patient should be placed in the Trendelenburg position after a midline incision has been made from the umbilicus downward toward the pubis for about 10 to 12 cm. After the peritoneal cavity is opened, the small intestine is packed off and the sigmoid and rectum are pushed to the left side and held there with a wide retractor. The uterus, adnexa and bladder may then readily be inspected and palpated to determine the extent of the malignant infiltration. One may also detect a complication, such as suppurating pus tubes, that can be remedied by a surgical procedure. The region of the lower two lumbar vertebrae and the upper part of the sacrum is exposed to view. In thin women, it is possible in some cases to see the presacral nerve immediately beneath the peritoneum. Whether or not the nerve is seen, the parietal peritoneum above and in the middle of the sacral promontory is elevated and incised with scissors. This incision is extended upward for about 4 or 5 cm. and for a similar distance down along the sacrum. When the peritoneal flaps are pulled aside, a fibrocellular connective tissue layer will be exposed, covered by more or less adipose tissue. This tissue can easily be separated from the peritoneum and the lower end of the aorta without danger. It is in this layer that the presacral nerve lies. With an aneurysm needle the tissue is elevated at the bifurcation

11. Ranson, S. W., in discussion on Sympathectomy, J. A. M. A. 56: 1978 (June 26) 1926; Surg., Gynec. & Obst. 50: 215 (Jan. 1 A) 1930.

12. Ferey, Daniel: Arch. franco-belges de chir. 30: 695 (Aug.) 1927.

of the aorta and the dissection is carried to a still higher level (fig. 2). As this is done, it will be found that in most instances the tissue spreads out triangularly. The middle sacral artery should be pushed away from the nerve, but if it is injured it can readily be ligated.

After the dissection is carried as high as it is desirable to go, the layer of nerve tissue is separated from the underlying tissue down past the sacral promontory into the pelvic cavity. In this region the plexus has divided into two hypogastric nerves; hence it is necessary to dissect one of these nerves at a time. At least 2 or 3 cm. of each hypogastric nerve should be resected in addition to 4 or more centimeters of the superior hypogastric and the intermesenteric plexuses. The fibrous tissue layer, which contains the hypogastric nerves, is much more resistant than that which contains the presacral nerve. As the dissection is carried out, nerve filaments projecting outward will be encountered. These should be followed as far laterally as possible before they are cut. In most instances, ganglions will be included in the resection. The dissected tissue should preferably be removed in one piece (fig. 3). It is not necessary or advisable to ligate the presacral nerve or the hypogastric nerves before cutting them, because the only blood vessels in intimate contact with them are insignificant vasa nervorum. In fact, Cotte is of the opinion that ligatures may be the origin of secondary pains. Very rarely does one encounter bleeding that requires more than simple temporary pressure to check it. (When the mesosigmoid is very short, care must be exercised to avoid injury to the inferior mesenteric vessels.) After the nerve is resected, the posterior parietal peritoneum is sutured with plain catgut and the abdominal wall is closed in the customary way. Since women with inoperable carcinomas are usually cachectic and prove to exhibit poor wound healing, it is advisable to use silkworm gut or other permanent suture material to aid in the closure of the abdominal wall.

RESULTS

We have thus far performed sympathectomy of the superior hypogastric plexus on thirteen patients who had inoperable carcinoma of the cervix. The pieces of tissue removed varied from 5 to 10 cm. in length. In every case, part of the excised tissue was studied microscopically and in every instance nerve fibers were found. In some cases, ganglions were seen in addition to the nerve fibers (fig. 4).

We were astonished at the brilliant results obtained, because all of the eleven patients who survived experienced instant relief following the operation. Even those who disturbed every one around them by their agonizing cries, in spite of large doses of narcotics, seldom required more than the mildest analgesic after the operation, except for the usual immediate postoperative discomfort. Three women had temporary diarrhea for a few days after the sympathectomy. Likewise, three women developed paresthesia in the back of the right thigh and popliteal space on the seventh and eighth days after operation. No bladder disturbances were observed. Two patients died, both on the twenty-fifth day after operation. One died of the cachexia she had before the procedure was carried out and the other of bronchopneumonia and cachexia. However, from the time of operation until death both patients had complete relief from the pain they suffered before operation. These two women were in extremely poor

condition at the time of the sympathectomy, and in both the entire procedure was carried out under local anesthesia. One of these women was the first one to be operated on after we worked out the technic on the cadaver. We selected those with the worst prognosis for our first cases. Not only are the eleven patients who survived free from pain but some have gained weight.

SUMMARY

At present there are only two satisfactory ways of relieving the intractable pain that is associated with inoperable malignant tumors in the pelvis; both are surgical. One, cordotomy, requires an extensive laminectomy, and unless the incision in the cord is accurately placed the pain may not be completely relieved or paralysis may result. The second operation, sympathectomy, may readily be performed by any gynecologist. The risk involved is slight, the operation is technically not difficult, local infiltration may be used for at least part of the procedure, and the operation enables one to inspect and palpate the carcinomatous involvement. The operation we advocate for the pain associated with inoperable carcinoma of the cervix consists of resection

Fig. 4.—Nerve fibers and ganglion cells at A.

of that portion of the sympathetic system known as the superior hypogastric plexus or the presacral nerve and also the two hypogastric nerves. The results obtained in thirteen cases were remarkable because all the patients experienced instant and complete relief from their suffering. We believe this operation should be performed on almost all women who suffer constant and excruciating pain as the result of inoperable cancer of the cervix.

185 North Wabash Avenue—25 East Washington Street.

Rheumatic Fever.—When the rheumatic subject is infected with the hemolytic streptococcus, the initial response is of the usual clinical character. If the infection is limited to the upper respiratory tract, recovery occurs within a few days. This illness, though mild, may nevertheless be the first phase in the development of a severe rheumatic attack. Following the subsidence of the local infection, the patient usually regains his customary health, and nothing abnormal is detected clinically. This quiescent interval of days or a few weeks represents the second phase in the evolution of the rheumatic process. The second phase persists until a rise in the titer of immune bodies is detected in the blood of the peripheral circulation.—Coburn, A. F., *Am. J. Dis. Child.* 45:933 (May) 1933.

Clinical Notes, Suggestions and New Instruments

TREATMENT OF SUBTROCHANTERIC, INTERTROCHANTERIC AND CERVICAL FRACTURES OF THE FEMUR

G. A. HENDON, M.D., LOUISVILLE, KY.

In treating cases of subtrochanteric, intertrochanteric and cervical fractures of the femur, I use a device made from beef bone which I call a key, and on which I rely exclusively for

Fig. 1 (case 1).—Comminuted subtrochanteric fracture of right femur: A, before operation; B, bone key in position and crutch union in four weeks; sufficiently strong union to permit walking on crutches.

immobilization. In the subtrochanteric cases, a posterior padded board splint is used, extending from the gluteal fold beyond the heel to facilitate moving the patient and changing his position in bed.

Fig. 2 (case 2).—Fracture of neck of right femur: A, before treatment; B, bone key in position four weeks after operation.

I now have a series of fifty-two cases; none of the patients have been confined to bed for more than four weeks. Union that permits walking on crutches is obtained in from three to four weeks. The following two cases are submitted, with illustrations, as examples.

CASE 1.—Mrs. R., aged 80, was blown down by the wind on the street and sustained a subtrochanteric, comminuted fracture,

as shown in figure 1 A. She was operated on the next day, the fragments were sawed smooth, and a bone key was driven in the direction of the long axis of the bone through the base of the neck of the femur at the digital fossa to engage in the medullary canal of the fragments below. Crutch union was obtained in four weeks, as shown in figure 1 B.

CASE 2.—C., a man, aged 78, with hemiplegia, fell out of his wheel chair and sustained a fracture on the paralyzed side through the neck of the femur near the head (fig. 2 A). The bone key was driven horizontally to the long axis of the leg, entering just above the base of the trochanter in passing through the neck and engaging the head. No external immobilizing method was employed. Union, as shown in figure 2 B, was obtained in four weeks. This man had been paralyzed and unable to walk, so no test of locomotion could be applied.

A more detailed description of the operation and its technic will be found in *THE JOURNAL*, Oct. 8, 1932, page 1224. This procedure offers relief not only for victims who sustain these fractures in advanced life but also for younger persons.

321 West Broadway.

DERMATITIS DUE TO NUPERCAINE

S. J. FANBURG, M.D., NEWARK, N. J.

Assistant Attending Dermatologist, University and Bellevue Hospital Medical College, New York

Within the past few years a new local anesthetic known as nupercaine has been introduced into this country. In Europe the same substance is known as percaine. It is recommended as producing anesthesia of prolonged duration. It is much more toxic than procaine, but, owing to the high dilutions in which it is possible to use nupercaine, the relative toxicity is about equalized.¹ Chemically, nupercaine is known as the hydrochloride of the diethylethylenediamide of butyloxycinchonic acid, and its structural formula is as follows:

It is not related to procaine, which is the monohydrochloride of para-aminobenzoyl-diethylaminoethanol. It is colorless, odorless, easily soluble in water or saline solution and is precipitated by alkali. Nupercaine is also recommended by the manufacturers for the relief of pruritus and is put up for that purpose in the form of an ointment of hydrous wool fat and petrolatum, containing a 1 per cent nupercaine base. Several fatalities and toxic manifestations with recoveries following the use of nupercaine by injection have been reported,² but I have been unable to find any previous report of dermatitis due to nupercaine ointment, though it is widely used.³

REPORT OF CASE

A middle-aged obese woman, referred to me by Dr. A. R. Chamberlain of Maplewood, N. J., had had a persistent eczema on the dorsal surfaces of the feet for several years. Her condition was otherwise negative except for a persistent achlorhydria. She had used nupercaine ointment at irregular intervals for several months to control the itching of the feet. In July, 1932, an erythematous vesicular eruption with swelling and pruritus developed on the feet, legs, thighs, arms and neck, which was thought to be due to contact with poison ivy. This eruption cleared up under soothing applications, but two or three subsequent attacks appeared in the same locations. Contact tests were carried out which gave strongly positive reactions to nupercaine. There were no reactions to hydrous wool fat or petrolatum. The nupercaine ointment was not used any more, and the skin condition improved. There was, however, another relapse, which was also traced to nupercaine. The patient had failed to discard a pair of bedroom slippers, the linings of

2. Keyes, E. L., and McLellan, A. M.: Further Experiences with Nupercaine, *J. A. M. A.* 96: 2085-2091 (June 20) 1931.

3. Since this report was submitted, R. W. Fowlkes has reported a case of dermatitis due to nupercaine (*J. A. M. A.* 100: 1171 [April 15] 1933).

which had become impregnated with the nupercaine ointment. Contact tests with the lining of the slippers resulted in positive reactions. After this, recovery was uneventful.

SUMMARY

A case of dermatitis was proved to be due to nupercaine ointment, by contact tests and recovery following withdrawal of the ointment.

31 Lincoln Park.

PERIPHERAL NEURITIS AS A SEQUELA OF
SPINAL ANESTHESIA

LEWIS H. LOESER, M.D., NEWARK, N. J.

During the past year I have encountered five cases of peripheral neuritis following spinal anesthesia. The frequency of this complication in my experience would suggest that it is a more frequent complication than the literature would indicate and that the presence of an inflammatory syndrome affecting isolated peripheral nerves has not been clearly recognized by other observers.

Case reports illustrating neurologic complications of spinal anesthesia are becoming quite numerous. Of these, the most common is that of paralysis of the sixth nerve. Blatt,¹ in 1929, had collected more than a hundred such case reports and the number is considerably higher at this date.

Numerous observers have reported clinical and postmortem changes in the central nervous system following spinal anesthesia. Pathologic changes have been reported by Nonne and Demme,² Spielmeyer,³ Lindemulder,⁴ MacLachlan⁵ and others. The observations are usually those of degenerative changes in the cord, demyelination and atrophy with evidence of glial reaction, together with a varying degree of meningeal reaction.

A certain amount of experimental work has been done to study the toxic effects of spinal anesthesia on the central nervous system. Wossidlo⁶ found definite changes in the ganglion cells of the spinal cords of his experimental animals. Davis and his associates⁷ in a thorough study of the subject reported various changes including:

1. A hemolytic and myelolytic action of the various drugs on the spinal cord.
2. A varying degree of meningeal inflammation as a constant finding.
3. Changes in the ganglion cells.
4. Swelling and fragmentation of the axis cylinders with degenerative changes in the fiber tracts. It was noted that the degenerative and cellular changes were inconstant in animals allowed to live ninety days or more but that the meningeal reactions were constant and marked.

Spielmeyer³ reported essentially similar observations in his experimental animals.

It may thus be seen that changes in the central nervous system following spinal anesthesia have been clearly recognized and studied. None of the observers have, however, noted specific changes in the peripheral nerves. Although such writers as Blatt,¹ Anderson,⁸ Dassen⁹ and Klein¹⁰ have mentioned the presence of lancinating pains, anesthetics and trophic changes, they are usually ascribed to changes within the spinal cord itself.

Lindemulder states that three of his patients had pain in the legs for several months with muscle tenderness. In view of my experience, I am inclined to question his interpretation of the cause of the pain. It is quite likely that the so-called

muscle pain and the hyperalgesias were due to inflammatory reactions in the peripheral nerves rather than to other causes.

In the cases I have seen, a constant syndrome was present. The neuritis followed the spinal anesthesia within a period of from one to three weeks. In each case the first symptoms noted were pain and paresthesias radiating along the course of the nerve. One nerve was, as a rule, greatly affected; the other nerves were only slightly involved. The ulnar nerve was involved in two cases, the radial in one, and the sciatic in two others. In no case was the condition bilaterally symmetrical.

The neuritis involves both sensory and motor fibers. Unmistakable sensory changes are quickly found in the distribution of the involved nerve. Trophic changes, such as muscle wasting, were seen in two cases. Muscular weakness and paralysis were unmistakable in two cases.

The condition usually persisted for a number of months and gradually improved. The nerves remained tender to pressure and tension for several months. Therapy was of little value, although local heat did tend to relieve the pain.

Five cases in all were seen, three involving the upper extremities and two the lower. The etiology of the cases involving the nerves of the lower extremities is always doubtful, since the question may arise of mechanical damage to the nerve roots by the lumbar puncture needle. I am therefore presenting the histories of three cases in which there can be no question of etiology:

REPORT OF CASES

CASE 1.—L. H. L. (the author) was operated on for acute appendicitis, June 10, 1932, under spinal anesthesia; 0.12 Gm. of procaine hydrochloride was injected in the second lumbar interspace. The operation and anesthesia were uneventful, but the convalescence was marked by severe pain in the back between the shoulder blades, and an inconstant, remittent fever. On the tenth day, moderate pain was noted along the right leg; this subsided within a few days. On the eighteenth day, pain and paresthesia were noted along the right radial nerve. The pain gradually became more severe, and by the twenty-third day a definite neuritis of the radial nerve was noted. The nerve was excruciatingly tender along its entire course, and anesthesia was present in the usual radial distribution. Movements of the arm, which tended to stretch the nerve greatly, increased the pain. Within a few days, slight involvement of the left ulnar nerve was noted; the involvement, however, was slight and passed away a few days later.

The condition gradually improved, and the pain subsided within a few weeks, though the presence of moderate nerve tenderness was noted a number of months later.

CASE 2.—K., a man, aged 52, had the right leg amputated because of arteriosclerotic gangrene. He received 0.1 Gm. of procaine hydrochloride in the third interspace. The operation and anesthesia were uneventful. On the fifth day after operation he complained of "queer sensations and electric shocks" in the fourth and fifth fingers of the right hand. Within a few days, a definite neuritis of the right ulnar nerve was present. The nerve was tender along its entire course. Sensory changes were typical of ulnar nerve involvement. Movements of the arm acutely increased the pain. There was weakness and atrophy of the muscles supplied by the ulnar nerve. The condition persisted over three months; the pain gradually improved and power returned to the involved muscles. No specific treatment was used.

CASE 3.—K., a man, aged 70, operated on for bilateral hernia, received 0.12 Gm. of procaine hydrochloride in the third interspace. Operation and anesthesia were uneventful. The convalescence was normal until the fifteenth day, when he first noted pain in the right arm. The pain was described as "pins and needles and electric shocks" radiating along the course of the ulnar nerve. The pain grew more severe and on several occasions was sufficient to cause him to faint. On examination, three weeks after the onset, he presented sensory changes of the ulnar type and showed marked paralysis and atrophy of all the muscles of the ulnar distribution. The ulnar nerve was extremely tender to touch and pressure. His case has not been followed, and nothing is known as to his recovery.

COMMENT

Two other cases were seen, one showing involvement of the sciatic nerve, the other presenting paresthesias and sensory changes of both lateral cutaneous nerves of the thigh. Their histories will not be given for the reason already stated.

The three cases cited illustrate the type of peripheral nerve involvement encountered after spinal anesthesia. Each case was thoroughly investigated for other possible etiologic agents, but no other factors were found. The cases are strikingly alike in regard to the latent period, mode of onset, distribution and duration. I am certain that if the syndrome is recognized it will ultimately be established that the presence of peripheral neuritis following spinal anesthesia is not an uncommon sequela. The pathologic condition is undoubtedly that of a low grade toxic reaction, originally within the spinal canal and extending later into the peripheral nerves. The original process is probably an arachnoiditis, the inflammatory process extending to the cord and ultimately involving the peripheral nerves, from one to three weeks after the anesthesia.

At this time, however, it is necessary to state that I do not regard this complication as a deterring factor in the use of spinal anesthesia. The advantages of spinal anesthesia under certain restrictions are so obvious that the presence of a complication such as the one described need not in any way invalidate the usefulness of the procedure.

SUMMARY

Five cases that are cited, three in detail, demonstrate the presence of peripheral neuritis following spinal anesthesia. In view of the long latent period, it is important for this complication to be recognized as a clinical syndrome and as a sequela of spinal anesthesia.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
H. A. CARTER, Secretary.

O₂-CO₂ METRIC TWIN UNIT FOR SMALL CYLINDERS ACCEPTABLE

The O₂-CO₂ Metric Twin Unit for Small Cylinders (McCormack Outfit), manufactured by the Foregger Company, Inc., 47 West Forty-Second Street, New York, is an apparatus for respiration therapy, particularly designed for resuscitation of the new-born or for use in the operating room to resuscitate an individual asphyxiated by gas.

Mechanically, it is well made, consisting of a stand and a base equipped with four rubber tired casters. The stand is provided with one control valve for oxygen and one control valve for carbon dioxide, each with two yokes to hold 2 (d) cylinders of 100 per cent oxygen and 2 (d) cylinders of 100 per cent carbon dioxide.

The meter jar combines both flow meters, oxygen with a scale maximum of 10 liters and carbon dioxide with a scale maximum of 1,500 cc. There are attachments, inhalers and rubber tubes to suit the preference of the operator. As a unit for resuscitation, it has the advantage of being absolutely independent in the establishment of a proportion of oxygen-carbon dioxide mixture. The gas mixture is easily adjustable, according to the desire of the operator.

To aid in the safety of the outfit as a resuscitation unit, an adjustable mercury gage is attached at the head of the flow meter unit, which practically eliminates the possibility of throwing an unduly high gas pressure on the lungs of the asphyxiated individual.

A unit was investigated by the Council. The report reads:

This apparatus has been used on twenty new-born infants who were in various stages of asphyxia at the time of birth. Their weight varied from 1,790 to 4,250 Gm. The menstrual age was estimated at 34 weeks in two instances; in all the

others gestation had advanced to 35 weeks in one, 36 weeks in one, 38 weeks in four, 39 weeks in four, and the remaining fetuses had reached term. The method of delivery varied; two were delivered by cesarean section, four were delivered spontaneously, and there were twelve low and two mid forceps. One of the births was the second of twins, in which solution of pituitary was given after the birth of the first fetus. This was one of the low forceps cases.

Five cases showed some sign of fetal distress prior to delivery, and in four of them meconium was visible in the amniotic fluid. Varying degrees of apnea or asphyxia were present at the time of birth. One infant was apneic, fifteen were livid, and four were pallid.

ETIOLOGY OF ASPHYXIA

The etiology of the asphyxia was obscured in five cases, although some sedative, usually morphine and scopolamine, together or alone, was given in all but two of the twenty cases.

ASPIRATION

Aspiration of mucus in varying amounts seemed to contribute to the asphyxia in seven cases and was complicated once by a tightly constricted cord about the neck and in a second case by considerable low lying cord. A cord tightly imprisoned beneath a nuchal arm occurred once uncomplicated by aspiration.

A prolonged second stage (four and one-third hours), followed by low forceps, was noted in one case. As already noted, 1 cc. of solution of pituitary before the delivery of a second twin (by forceps) caused some fetal distress in one instance.

TRAUMA

Trauma occurred in mild degree in four cases, and in one instance it was moderate. In two of these instances, the baby appeared to be narcotized also, and in a third it was premature (35 weeks).

FETAL CIRCULATION

No definite observation of the fetal circulation at birth was made in five cases. In five other cases it was described as "slow" or "fair." In two cases each the heart beats were 60, 70 and 80, respectively, before treatment and 90 in one case. In the three remaining cases the fetal circulation was described as "good."

NATURE OF RESPIRATION BEFORE TREATMENT

The nature of respirations at birth was observed as follows: none (eight); gasps—usually sporadic (five); poor (three); fair (three), and normal, but with other evidences of apnea (one).

PHARYNGEAL REFLEX

The pharyngeal reflex was observed in seventeen cases, being good in nine. It was fair in two, poor in four, and absent in two. It seemed to be a good prognostic sign as to the degree of asphyxia.

PERCENTAGE OF OXYGEN AND CARBON DIOXIDE

The following percentages of carbon dioxide and oxygen were used: 70 per cent oxygen and 30 per cent carbon dioxide, 3 cases; 90 per cent oxygen and 10 per cent carbon dioxide, 4 cases; 93 per cent oxygen and 7 per cent carbon dioxide, 7 cases; 95 per cent oxygen and 5 per cent carbon dioxide, 1 case; pure oxygen, five cases.

The pure oxygen promptly restored color and circulation after two or three breaths were inaugurated by artificial respiration. Ninety-five per cent oxygen and 5 per cent carbon dioxide seemed to act in the one case as oxygen, and 93 per cent oxygen and 7 per cent carbon dioxide were very much the same. The 70 per cent oxygen and 30 per cent carbon dioxide seemed to stimulate rapid and deeper respirations. In eleven cases the anesthesia used was ethylene and oxygen. In one case time did not permit inhalation anesthesia. The two cesarean sections were done under local (procaine infiltration) anesthesia.

The duration of labor was not recorded exactly in one case. In the other seventeen (two sections, elective) the first stage averaged about thirteen hours and the second approximately one hour and forty minutes. The total time in labor thus averaged close to fifteen hours.

TIME RELATION TO TREATMENT

Treatment was given in from one to sixteen minutes after birth, the average interval being four minutes. Fair respirations occurred before treatment in six instances, but in the other fourteen it was observed that regular satisfactory respirations were established in from one-half to eight minutes after the administration of the gas was started. The average interval was three minutes and five seconds.

RESULTS

Treatment was continued from two to fifteen minutes before the baby was thought to be in satisfactory condition to do without the gas. The average period of treatment was five minutes and thirty-one seconds. The total period of observation for each baby varied from six to fifty minutes, averaging twenty-three minutes.

Fifteen babies left the birth room in good or excellent condition; the other five left in fair condition. Two of these received repeated gas treatment (90 per cent oxygen and 10 per cent carbon dioxide) on the floor but both died.

Seventeen babies were discharged from the hospital in good condition after uneventful progress. Three babies died; all were premature, one at 34 weeks, one at 35, and one at 38 weeks' gestation by menstrual history. In two there was severe toxemia.

PROTOCOLS OF DEAD BABIES

Baby R.: The mother, an octipara, had a marked hypertension (from 200/100 to 250/140), with permanent kidney involvement. When it became apparent that she would not carry to term, a cesarean section and sterilization were done at 35 weeks. While the infant seemed to respond well clinically to the inhalations (70 per cent oxygen and 30 per cent carbon dioxide first, followed by repeated 95 per cent oxygen and 5 per cent carbon dioxide on the floor), with good color and fairly deep respiratory excursions, it died after about eight hours and showed an almost complete bilateral congenital atelectasis at necropsy.

Baby Z.: Cesarean section was done at 34 weeks because of a severe progressive toxemia, in spite of about six weeks' conservative treatment. There was fair response to gas but there were signs of cerebral hemorrhage, bulging fontanels, cyanotic spells, and bloody cerebral spinal fluid. The clinical diagnosis was prematurity and cerebral hemorrhage. No necropsy was done.

Baby K.: Spontaneous delivery occurred at 38 weeks (the baby's weight was only 1,927 Gm.). There were forty-five minutes of hard second stage pains, with poor cooperation in expulsive effort, due, probably, to scopolamine. Necropsy showed cerebral hemorrhage besides the prematurity.

The cry was poor in the three fatal cases and in one infant that survived; all of the other babies had a vigorous cry on leaving the birth room.

There were no eye changes (nystagmus, pupillary changes) paralysis or evidences of trauma noted, except for rather deep forceps marks in one instance.

The results of gas administration with this machine seem quite satisfactory, except in the case of the premature infant who died showing almost complete atelectasis after an apparently good response. Perhaps this tends to support the more recent view that the aeration of the lungs of new-born infants is a slower process, physiologically, than formerly surmised and cannot be hurried by artificial means. In one case the response to the gas was remarkably rapid and gratifying.

The claims of the manufacturers of this apparatus in emphasizing the advantage in exact regulation of percentage of carbon dioxide and oxygen seem well founded.

Percentages can readily be changed as described on the same patient, with little or no loss of time in therapy.

With reasonable care there should be no mechanical difficulty in using this machine. It appeared to be sturdy and reliable.

The Council on Physical Therapy declares the O₂-CO₂ Metric Twin Unit for Small Cylinders (McCormack Outfit) acceptable for inclusion in the list of acceptable devices.

O₂-CO₂ Metric Twin Unit for Small Cylinders (McCormack Outfit).

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
PAUL NICHOLAS LEECH, Secretary.

BURNHAM'S SOLUBLE IODINE AND BURNHAM'S IODINE OINTMENT NOT ACCEPTABLE FOR N. N. R.

Burnham's Soluble Iodine, marketed by the Burnham Soluble Iodine Co., Auburndale, Mass., was rejected by the Council in 1915 (*THE JOURNAL*, May 15, 1915, p. 1673) as a semisecret preparation marketed by means of extravagant and dangerous therapeutic claims.

In 1929, a communication was received from the consulting pathologist of the Burnham Soluble Iodine Co., which seemed to indicate that the firm was anxious to make its product eligible for admission to New and Nonofficial Remedies. The product was stated to have the following composition: "Free Iodine 3.5%, Hydrogen Iodide 1.5%, Total Iodine 5.0%, Ethyl Alcohol 42.0%." The pharmacologic action and therapeutic indications were stated to be essentially those of iodine. As a result of the Council's criticisms of the claims advanced for the product, proposed revisions of the advertising material were submitted from which the objectionable features had been essentially removed. The special claims were restricted to the statement that many physicians object to alkaline or complex iodides and that such physicians should consider Burnham's Soluble Iodine. After sufficient time had elapsed to indicate that the firm did not intend to carry the proposed revisions of the advertising into effect, a letter of inquiry was addressed to the Burnham Soluble Iodine Co. In reply, the firm wrote as follows: "Because of the conditions required for recognition of our 'physiologically available active free iodine' (Burnham's Soluble Iodine), in our last correspondence [with the Secretary] and also encouraging developments in research work in its use orally, intravenously and locally, which we hope to continue for some time, we have decided to take no further action at present with the Council towards recognition." The current advertising which is issued for Burnham's Soluble Iodine shows that the proposed revisions of the advertising have not been carried into effect but that instead the product is being marketed with claims which are as unwarranted as those which caused the Council to reject the product in 1915.

The claims which are discussed below appear in a circular entitled "Burnham's Soluble Iodine for Intravenous and Intramuscular Use." "For a number of years, discriminating practitioners have reported unusual, and even startling results, with Burnham's Soluble Iodine used either intravenously or intramuscularly, indicating that they had often proved the superiority of this treatment, especially in pneumonia and acute infections. Where there was danger of collapse and the quickest intensive effect was imperative, they found that this treatment often proved to be a life saver." The Council knows of no reliable evidence in support of such a claim. "In contrast to organic and other iodine compounds this FREE iodine, to a much larger extent, is changed into iodates in the tissues." There is no satisfactory evidence that iodates are any more effective than simple iodides in the conditions in which iodine is indicated. "Arterio-Sclerosis: Edwin Matthew, M.D., F.R.C.P. . . . 'The action of iodides, in high blood pressure depends on the iodine content, and for beneficial results there must be a certain and sufficient amount of iodine present' (and physiologically available)." It is obvious that the author of this statement did not refer to free iodine but to total iodine in the form of iodide. This is apparently an attempt to distort the original meaning to suit the purpose of the advertisement; note the parenthetical addition at the end. "An exhaustive review of the literature indicates beyond doubt that iodine intravenous (and therefore also intramuscular), has established its value in a large number of acute and chronic infections. Among these are: influenza, pneumonia, syphilis, plague, tularmia, erysipelas, typhoid, malaria, chronic joint lesions, kala-azar, and local and general infections with the pathogenic cocci." Overlooking for the moment the suggestion that intramuscular and intravenous injection are necessarily equivalent, the inference is that the

"established . . . value" is great whereas actually the opposite is the case; in some of the conditions enumerated iodine may really be dangerous. "If there is idiosyncrasy to iodine, or veins are small, dilute with equal parts sterile water to avoid possible sclerosis of the vein." The implication that a dose of iodine, if properly diluted, may be administered to an individual with idiosyncrasy to iodine, is absolutely indefensible. The total dosage in any event would be the same and the liability to severe systemic reactions would not be diminished by dilution. In "acute sepsis" it is recommended that 15 to 50 cc. be administered intravenously every one to three hours "until temperature is under control." This recommendation appears reckless.

In another circular "The Therapy of Free Iodine versus Iodides—Organic and Inorganic" the following claims are made: ". . . one would not expect the use of iodides or organic iodine compounds locally to replace the direct germicidal effect of FREE iodine. The same analogy holds for the use of free iodine for internal medication." As was pointed out in the Council's report in 1915, "the free iodine in Burnham's Soluble Iodine must act in the system as an iodide, and the whole iodine content, to furnish a correct estimate of the value of the preparation, should be reckoned as an iodide." The lapse of eighteen years since this statement was made has brought to light no conflicting testimony.

"One of the great drawbacks to the use of alkali salts of iodine, is their rapid elimination from the system." No evidence is furnished that Burnham's Soluble Iodine is any less rapidly excreted than the alkaline iodides.

Many other claims are made, some so absurd as to defy serious consideration; it would serve no useful purpose further to discuss this "literature." There is no evidence that Burnham's Soluble Iodine will do anything more than potassium iodide or, if the physician prefers, compound solution of iodine.

Recently the firm has marketed Burnham's Iodine Ointment, said to contain free iodine, salicylic acid, methyl salicylate, menthol and anesthesin (ethyl aminobenzoate-U. S. P.) in a petrolatum base, all in unstated proportions. This appears to be an unscientific preparation containing an excessive number of active ingredients, the presence of only one of which is indicated in the name. As with Burnham's Soluble Iodine, many extravagant claims are made for this ointment.

The Council finds Burnham's Soluble Iodine and Burnham's Iodine Ointment unacceptable for New and Nonofficial Remedies because they are semisecret preparations marketed with extravagant and unwarranted therapeutic claims.

BACILLUS BULGARICUS AND KEFIR FUNGI PREPARATIONS OMITTED FROM N. N. R.

For some years the Council has retained in New and Nonofficial Remedies the accepted *Bacillus bulgaricus* preparations only on condition that claims for them were limited to recommendations for the preparation of soured milk and provided especially that no claims were made for the implantation of *B. bulgaricus* in the intestine. The Council further held that milk soured by the addition of pure lactic acid has essentially the same therapeutic effect as milk soured by bacterial fermentation (Lactic Acid-Producing Organisms and Preparations, New and Nonofficial Remedies, 1933, p. 246).

Lactic acid is a simple substance, easily purchased, and milk soured with it seems to have all the therapeutic properties of milk fermented by *Bacillus bulgaricus* and Kefir fungi. The Council deemed it unwise to retain in future editions of New and Nonofficial Remedies preparations of *Bacillus bulgaricus* and of Kefir fungi, since in addition to being thus superfluous, they are in general indefinite, complex and variable. The Council held that, if milk products prepared by these organisms have special qualities of palatability and digestibility and are of distinct nutritive value, they should be considered as food adjuncts rather than remedial agents and as such be referred to the Committee on Foods.

The Council voted to omit all *Bacillus bulgaricus* preparations and Kefir fungi preparations from New and Nonofficial Remedies. These include: *Bacillus Bulgaricus-Squibb*, B. B. Culture and Kefir Fungi.

Committee on Foods

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

VITAMIN D FORTIFIED PASTEURIZED MILK (150 VITAMIN D UNITS PER QUART) ADVERTISING OF W. J. KENNEDY DAIRY COMPANY

Distributor.—W. J. Kennedy Dairy Company, Detroit.

Description.—Advertising for hotted pasteurized cow's milk fortified with vitamin D (extract of cod liver oil); contains 150 vitamin D units (Steenbock—defined by the Council on Pharmacy and Chemistry of the American Medical Association, New and Nonofficial Remedies, 1933, page 428) per quart.

Preparation.—The milk complies with the analytic and bacteriologic requirements specified by the laws of the state of Michigan and the city of Detroit or other municipalities in which it is distributed.

The vitamin D concentrate added to the milk is supplied by the National Oil Products Company of Harrison, N. J., and contains a guaranteed vitamin D content per definite volume. The vitamin D concentrate is manufactured under license granted by University Patents, Inc., New York City, a subsidiary of Columbia University (patent No. 1,678,454).

Sufficient vitamin D material (to give the required number of D units per quart of milk) is admixed with a small portion of milk (one quart) by means of a small viscolizer; this thoroughly incorporates the vitamin D material into the cream of the milk. This small amount (one quart) of vitaminized milk is introduced into the whole batch, which is thoroughly agitated, pasteurized by the standard procedure of holding at 61 C. for not less than forty minutes, immediately cooled to 4 C., and automatically bottled. The bottles are closed with a seal-cap and a hood-cap held in place by wire.

Analysis (submitted by distributor).—

| | per cent |
|-------------------------|----------|
| Total solids | 12.6 |
| Water | 87.4 |
| Mineral ash | 0.7 |
| Milk fat | 3.8 |
| Protein (N × 6.38) | 3.2 |
| Lactose (by difference) | 4.9 |

Calories.—0.7 per gram; 20 per ounce.

Vitamins.—The vitamin D concentrate used in the preparation of this vitamin D milk is biologically tested. Arrangements have been made whereby the Biological Department of Michigan State College and an independent laboratory will regularly assay market samples for vitamin D. Biologic examination shows a content of 150 Steenbock D units per quart.

Claims of Manufacturer.—A rich source of vitamin D; one quart is equivalent in vitamin D content to 2½ teaspoonfuls of good grade cod liver oil (60 Steenbock vitamin D units per teaspoon).

BLAIR'S CERTIFIED SOUTHERN TYPE FLOUR (BLEACHED)

Manufacturer.—Blair Milling Company, Atchison, Kan.

Description.—A hard winter wheat "standard patent" flour; bleached.

Manufacture.—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one-ninth ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (1 pound to 50 barrels of flour).

Claims of Manufacturer.—For general baking in the home.

HEINZ STRAINED VEGETABLE SOUP

WITH CEREALS AND YEAST EXTRACT

Manufacturer.—H. J. Heinz Company, Pittsburgh.

Description.—Comminuted and strained cooked mixture of carrots, celery, potatoes, tomatoes, onions, rice and pearl barley, with a small amount of autolyzed yeast concentrate, retaining in high degree the mineral and vitamin content of the natural products; no added sugar or salt; the coarser fibrous portion is removed.

Manufacture.—A mixture of rice and pearl barley, which has been sorted for removal of defective kernels, is boiled with water until soft enough to be sieved. A variety of vegetables, consisting largely of carrots, celery and potatoes with smaller proportions of tomatoes and onions are properly trimmed and washed, are placed in a closed cooker and cooked under slight pressure with exclusion of air. At the finish of the cooking a small amount of autolyzed yeast concentrate is added to enrich the flavor and the content of vitamins B and G. The cooked vegetables are mixed with the cooked cereal mixture. The extractives are retained with the solids. The entire mixture is comminuted, processed and packed as described for Heinz Strained Spinach (THE JOURNAL, Feb. 25, 1933, p. 577).

| <i>Analysis</i> (submitted by manufacturer).— | | per cent |
|---|--------|----------|
| Moisture | 88.3 | |
| Total solids | 11.7 | |
| Ash | 0.7 | |
| Sodium chloride | 0.2 | |
| Fat (ether extract) | 0.1 | |
| Protein (N \times 6.25) | 1.8 | |
| Reducing sugars as invert before inversion | 1.1 | |
| Sucrose | 0.8 | |
| Crude fiber | 0.4 | |
| Carbohydrates other than crude fiber (by difference) .. | 8.7 | |
| Calcium (Ca) | 0.03 | |
| Phosphorus (P) | 0.03 | |
| Iron (Fe) | 0.0015 | |

Calories.—0.4 per gram; 11 per ounce.

Vitamins.—The method of preparation efficiently protects the natural vitamin values. The strained mixed vegetable soup is a good source of vitamins A, B and G and a fair source of C.

Claims of Manufacturer.—For table use, but especially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving. The natural mineral and vitamin values are efficiently retained.

FORCE TOASTED WHOLE WHEAT
FLAKESWITH HARSHTEST BRAN REMOVED (FLAVORED WITH
SUGAR, SALT AND MALT SYRUP)*Manufacturer.*—Hecker-H-O Company, Inc., Buffalo, N. Y.

Description.—Cooked and toasted flaked whole wheat with only the outer bran layer removed; flavored with sucrose, salt and malt syrup.

Manufacture.—Cleaned wheat is tempered with water to facilitate removal of the outer layers of the bran, which are scoured off in a special machine; the wheat with water, brown sugar, malt extract and salt in definite proportions is cooked in closed rotating drums at 10 to 20 pounds pressure for two hours. The cooked material is partially dried with hot air, cooled with cold air, broken up into granules, allowed to stand from twelve to eighteen hours, aspirated to remove fine material, flaked between steel rolls, dried in steam heated driers, toasted in revolving gas heated drums, passed over special separators to remove fine material and off-sized flakes, cooled, and packed in wax paper bags in cartons.

| Crude fiber | 1.2 | |
| Carbohydrates other than crude fiber (by difference) .. | 79.5 | |
| Iron (Fe) | 0.015 | |

Calories.—3.7 per gram; 105 per ounce.

Claims of Manufacturer.—Only the coarser outer bran layers of the wheat are removed.

LARSEN'S STRAINED TOMATOES

UNSEASONED—READY

FOR USE

Manufacturer.—The Larsen Company, Green Bay, Wis.

Description.—Sieved tomatoes prepared by efficient methods for retention in high degree of the natural mineral and vitamin values of the raw tomatoes. No added sugar or salt.

Manufacture.—Fresh ripe tomatoes are washed, sorted, peeled, carefully inspected for removal of any undesirable material and puréed in an atmosphere of steam in a paddle type puréeing machine of monel metal with a bronze rotor. The puréed tomatoes are concentrated at 82 C. to a desired consistency in covered aluminum kettles, and automatically filled into washed cans, which are sealed and processed for twenty-five minutes at 100 C.

| <i>Analysis</i> (submitted by manufacturer).— | | per cent |

| Protein (N \times 6.25) | 1.4 | |
| Crude fiber | 0.4 | |
| Carbohydrates other than crude fiber (by difference) | 5.5 | |

Calories.—0.3 per gram; 9 per ounce.

Vitamins.—The methods of preparation, sieving and processing are efficiently protective of the natural vitamins.

Claims of Manufacturer.—For all table uses of strained tomatoes, but especially intended for infants, children and convalescents and for special "smooth" diets. Only warming is required for serving. The natural mineral and vitamin values are retained in high degree.

DIP CANDY

Manufacturer.—The Curtiss Candy Company, Chicago.

Description.—Sweet chocolate covered candy bar containing sucrose, corn syrup, coconut butter, egg albumin, cocoa, salt, gelatin, vanillin and coumarin.

Manufacture.—The ingredients in definite proportions are whipped to a spongy mass, which is spread on steel plates; the mass is solidified in refrigerated rooms, cut into bars of desired size, automatically covered with sweetened chocolate, cooled and wrapped.

| <i>Analysis</i> (submitted by manufacturer).— | | per cent |

| Carbohydrates (by difference) | 84.1 | |

Calories.—4.4 per gram; 125 per ounce.

FISHER'S CAKE FLOUR (BLEACHED
AND MATURED)*Manufacturer.*—The Fisher Flouring Mills Company, Seattle.

Description.—"Short patent" flour milled from a blend of soft red and white wheats; bleached and matured.

Manufacture.—Selected soft red and white wheats are cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with mixtures of chlorine and nitrosyl chloride (1½ ounces per 196 pounds), and benzoyl peroxide and calcium phosphate (1 pound per 28 barrels).

Claims of Manufacturer.—Especially adapted to cake and pastry baking.

OMAR FINE BREAD. LONG SLICED

Manufacturer.—Omar Baking Company, Omaha, Neb.; Milwaukee, Wis.; Columbus, Ohio; Indianapolis, Ind.

Description.—A white sliced bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817); prepared from flour, water, powdered skim milk, lard, dextrose, beet sugar, salt, yeast, diastatic malt extract, and a yeast food containing potassium bromate, ammonium chloride, sodium chloride and calcium sulphate.

SATURDAY, JULY 1, 1933

THE FIRST HEART SOUND

For more than a century the heart sounds have played an important part in medical diagnosis. Their value to the clinician was stressed particularly by Laënnec, who devised the fundamental features of modern auscultation early in the nineteenth century. The association of the second sound with the closure of the semilunar valves is generally accepted. According to the familiar explanation given in a widely used textbook,¹ the usual view is that the sound is due ultimately to the vibrations set up in these valves by their sudden closure; these vibrations are transmitted to the column of blood in the aorta (or pulmonary artery) and then to the intervening tissue of the chest wall.

The so-called first sound of the heart has not yielded so readily to a satisfactory explanation. It is admittedly related in some way to the function of the auriculoventricular valves. The chief difficulty in defining the cause of the sound with precision lies in the inability to dissociate convincingly the valvular factors involving vibration of the valves from the muscular features involving vibration of associated contracting muscle masses.² A recent writer³ has briefly summarized the views as follows: The first heart sound is supposed to originate in the closure of the auriculoventricular valves, in the friction of contracting ventricular muscle, in the change in tension in the aorta and pulmonary artery, in the change in tension in the coronary vessels and, finally, according to the thesis accepted by both Schutz and Frey, in physical changes in tension of the ventricles during the rise of intraventricular pressure.

In the customary explanations of the first heart sound, there is no clarity as to how the muscle or valves set up audible vibrations. More than a hundred years ago Rouanet⁴ wrote, in a Paris thesis: "From many experiments I have learned that any membrane, passing

from flaccidity to tension suddenly, always makes a sound. . . . The auriculoventricular valves present conditions which are most favorable for the production of sound; they are thin and tough and do not stretch; they pass instantly from the most complete flaccidity to sudden and violent tension." The assumptions thus stressed have been put to test recently by Dock³ at the Stanford University Medical School in San Francisco. His experiments on the exposed hearts of laboratory animals convince him that there is no muscular element in the first heart sound and that ventricular systole produces no audible vibrations, in either empty or full hearts, if tensing of the auriculoventricular valves is prevented. Dock's thesis is that the first heart sound is due to the sudden putting under high tension of the previously slack fibers of the auriculoventricular valves. If the valves are closed and the slackness is taken up gradually before ventricular systole occurs, the intensity of the sound is greatly diminished. The factors determining loudness of the first sound are, therefore, the degree of tension in the valves when ventricular systole occurs and (less important) the rate of rise of intraventricular tension. Heretofore it has been difficult to account for the accentuated heart sound heard in some cycles in cases of complete heart block or in cases of mitral stenosis. A tenable explanation is brought nearer by the studies of Dock.

EMERGENCY RELIEF ACT AND MEDICAL SERVICE

Five hundred million dollars was made available for the relief of needy and distressed people by the Federal Emergency Relief Act, approved by the President, May 12. This supplements the unexpended balance remaining from three hundred million dollars provided for the relief of destitution and distress by the Emergency Relief and Construction Act of 1932. These huge appropriations indicate the magnitude of the problem that confronts the country. Whereas the earlier act did not indicate clearly whether the money made available could be used for the alleviation of suffering and distress due to illness and injury not directly traceable to unemployment, the act recently passed seems clearly to make adequate medical and hospital services available for the relief of needy sick and injured persons regardless of the origin of their diseases and injuries.

The provisions of the Federal Emergency Relief Act of 1933, under which the federal government is now aiding the states in their efforts to alleviate distress, replace similar provisions of the Emergency Relief and Construction Act of 1932. The money made available by the earlier act could be used only "in furnishing relief and work relief to needy and distressed people and in relieving the hardship resulting from unemployment." This ambiguous phraseology gave rise to doubt whether needy and distressed people were entitled to

4. Rouanet, J., quoted by Dock.

relief when their needs and distress could not be traced directly to unemployment. The language of the Federal Emergency Relief Act of 1933, when read as a whole, does not permit such narrow construction. It authorizes grants to the several states "to aid in meeting the costs of furnishing relief and work relief and in relieving the hardship and suffering caused by unemployment in the form of money, service, materials, and/or commodities to provide the necessities of life to persons in need as a result of the present emergency, and/or to their dependents, whether resident, transient, or homeless." The nature of the emergency to be relieved is stated in section 1 of the act as "a serious emergency, due to widespread unemployment and increasing inadequacy of state and local relief funds, resulting in the existing or threatened deprivation of a considerable number of families and individuals of the necessities of life, and making it imperative that the federal government cooperate more effectively with the several states and territories and the District of Columbia in furnishing relief to their needy and distressed people." Certainly this language will neither justify nor excuse a construction of the act that denies the aid of federal funds to all ill and injured persons who are in need, without regard to the origin of their illness and injuries.

Physicians and hospital administrators have already seen numerous instances of distress due to illness and injury not traceable directly to unemployment without relief because, it was said, federal loans could not be used to aid in the maintenance of hospitals or in furnishing medical relief. Now that federal funds have been made available, physicians and hospital administrators, wherever state and local funds are inadequate to provide relief, should lead the way in asking the governors of their respective states, if they have not already sought federal aid under the Federal Emergency Relief Act of 1933, to seek such aid at once. If the state has already obtained a grant under that act, the use of it to afford relief for illness and injury may be demanded. The first effective move in any case must be made by the governor of the state, who alone is authorized by the act to make application for a federal grant.

PLACENTAL ANTIBODIES

The majority of infants under 6 months of age are apparently immune to measles, scarlet fever, diphtheria and poliomyelitis. This immunity is usually explained as the result of transmission of antibodies through the placenta, followed by postnatal transmission in colostrum and milk. In some cases, however, this simple explanation seems inadequate; infants, for example, appear immune to scarlet fever and diphtheria, whereas their mothers are demonstrably susceptible to these diseases. Again, umbilical blood from some new-born infants will neutralize poliomyelitis virus in spite of

the fact that the blood of their mothers is without demonstrable virucidal properties. To account for such paradoxes, certain immunologists have postulated the existence of a special mechanism in infants, a "tissue immunity" associated with the rapid multiplication of fetal and infantile cells. If this fetal mechanism is a reality, the placenta presumably might be the source of antibodies useful in treatment.

Applying this conception, McKhann and Chu¹ of the department of pediatrics at Harvard Medical School prepared aqueous extracts of normal human placenta and isolated sterile human globulins from these extracts. The globulins thus obtained were found to be nontoxic for guinea-pigs and rabbits. Intradermal and subcutaneous injections into members of the laboratory staff were also without toxic effects. The preparations contained no demonstrable traces of estrus-producing or ovary-stimulating hormones.

Tests of the antibody content of these placental extracts gave positive results. As little as 0.00156 cc. of a 4.2 per cent globulin solution, for example, would completely neutralize a necrotizing dose of diphtheria toxin, as shown by subsequent intradermal injection into guinea-pigs. The globulins also neutralized poliomyelitis virus *in vitro*, as shown by subsequent intracerebral inoculations of monkeys. Furthermore, the globulins would blanch scarlet fever rash, in some instances the blanching effects being superior to those obtained with specific scarlet fever antitoxin.

The most striking results, however, were in the apparently successful prophylaxis of measles. "In the course of hospitalization for other causes," they say, "fifteen children, nonimmune to measles, became thoroughly exposed to the disease, in seven cases so closely exposed that infection would seem to have been a certainty. These children received placental protein extracts by intramuscular injection within five days after the exposure to measles. Fourteen of the patients who received the placental extracts escaped measles, while one child, after a period of incubation prolonged to nineteen days, had a mild, modified form of the disease. In contrast to these children who received placental extracts, three children, similarly exposed to measles, received, on the fourth day of exposure, 30 cc. each of adult whole blood by intramuscular injection; in all, modified measles developed. Two children who through faulty histories were thought to have had measles and who received no serum contracted typical measles. The experience with these five children indicates the thoroughness of the exposure of the total group and justifies the conclusion that some, at least, of the children who received placental protein extract were protected."

The Boston investigators have carefully avoided theoretical discussion as to the probable nature of their globulin preparations, which, from their published tech-

1. McKhann, C. F., and Chu, F. T.: *J. Infect. Dis.* 52: 268 (March-April) 1933.

nic, must have been a mixture of maternal and fetal blood proteins and placental products. Certainly their results open a new approach to the prophylaxis and treatment of infectious diseases.

POTENTIAL ALKALINITY OF FRUIT JUICES

The salts of the organic acids in some of the common fruits and vegetables, as has frequently been demonstrated, are converted to bicarbonate in the course of metabolism. The alkali reserve of the body is thereby augmented to the point at which there is an apparent surplus of fixed base; as a consequence the hydrogen ion concentration of the urine is decreased, ammonia is diminished and the titratable acidity tends to fall. The exigencies of maintaining an adequate supply of base being what they are ordinarily, the foregoing facts have gradually become recognized for their therapeutic value. Although it is known that acetic, lactic, citric and malic acids are oxidized to bicarbonate to a greater or less extent under normal conditions, there is little doubt that other acids occurring in fruits and vegetables probably behave in like manner. On the other hand, experience has shown that certain distinctly "acid" fruits, such as plums, cherries, cranberries and prunes, are exceptions to the rule, since the urine acidity is increased after they are consumed in sufficient quantity. Benzoic acid was early suggested as the cause for this acidity, but it has recently been shown by Kohman and Sanborn¹ that quinic acid is largely responsible for the acidifying effect of prunes and cranberries.

In view of the increasing use of orange and tomato juice in the diet, significance attaches to the study of Saywell and Lane² on the comparative effects of these food materials in metabolism. When 1,000 Gm. either of tomato juice or of orange juice was added to a basal ration of human subjects over a period of five days there was in both cases a progressive decrease in acidity of the urine as shown by the hydrogen ion concentration and the titratable acidity and a decrease in the ammonia. This tendency toward alkalization was more pronounced with tomato juice than with orange juice. A study of the ash of the fruits indicated that in tomatoes there is more water soluble alkalinity than in oranges. Determinations of the extent of oxidation of the organic acids in the two fruit juices indicated that this change took place to the extent of over 90 per cent, with the orange juice somewhat superior in this respect.

These studies serve to extend similar observations on pineapples, figs and other fruits and vegetables. Given certain kinds of readily available organic acid salts, the body converts the base to the physiologic alkali bicarbonate. It has been stated³ that it is practically impos-

sible to overstep the capacity of the organism to bring about this type of oxidation. In this connection may be emphasized, too, the pleasant and surprisingly efficient quality of certain of nature's dietotherapeutic measures, for along with the indispensable base in fruits and vegetables there are provided pigments and vitamins and doubtless other as yet unappreciated essentials of nutrition.

Current Comment

LETTUCE AND THE REQUIREMENT FOR CALCIUM

The attention that has been devoted to the biochemical importance of calcium in recent years is justified both by the functional significance of calcium in the organism and by a consideration of the available supply under ordinary circumstances. This element enters into the structure of the body, about 99 per cent of the content of calcium being present in the skeleton. Furthermore, such fundamental reactions as the clotting of blood and the orderly operation of the muscle-nerve mechanism are dependent on the presence of calcium in normal concentration. However, it has been pointed out¹ that the ordinary American dietary is more likely to be deficient in calcium than in any other nutritive essential. It has thus happened that special attention is usually given to the calcium content of the food materials making up the diet. Milk contains somewhat more than one gram of this element per liter, and both milk and milk products have long been recognized as exceptionally valuable sources of lime in the diet. For practical reasons it is often impossible to satisfy the total daily requirement for calcium with milk. Thus it is important to evaluate other components of the diet in this connection and to determine the availability of the calcium determined in them. In a recent study on human subjects, Mallon, Johnson and Darby² have compared the retention of the calcium of leaf lettuce with that of milk, when the greater part of the lime was provided by either of the two food materials and the remainder of the diet was adequate. The data indicate that the retention of calcium was markedly greater when provided by lettuce than when the same amount was consumed as milk. These observations might serve as a challenge to the superiority of milk as a source of lime until it is realized that the daily consumption of about a peck of lettuce was required to equal the calcium of the amount of milk ingested—a little more than half a pint. Similar difficulties of a strictly practical nature militate against entire dependence on sources of calcium other than milk. However, these studies, along with those of similar nature carried out on other leafy and root vegetables, emphasize the fact that, when necessary, other food materials can at least supplement, if not entirely satisfy, the daily requirement for calcium.

PROCEEDINGS OF THE MILWAUKEE SESSION

MINUTES OF THE EIGHTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT MILWAUKEE, JUNE 12-16, 1933

(Continued from page 2023, volume 100)

NEW BUSINESS

Report of Committee on Mental Health

The Secretary presented the printed report of the Committee on Mental Health, which was referred to the Reference Committee on Medical Education.

Petition for Section on Stomatology

Dr. Grant C. Madill, New York, read the following petition from the American Society of Stomatologists, which was referred to the Council on Scientific Assembly:

To the Members of the House of Delegates:

As director of the American Society of Stomatologists and for the profession of stomatology as represented by the subjoined signers of this petition, I hereby ask for recognition of our standing as practitioners of a specialty in medicine.

At no other time in the history of American medicine and dentistry has the lack of recognition by the American Medical Association of stomatology as a specialty presented so significant a problem of vital concern to the dental surgeon, to the public, and possibly to the general physician, the surgeon and the worker in the accredited medical specialties.

Without recognition, the oral clinician is deprived of the opportunities which he would otherwise have of improving the quality of his services to his patients in particular and to the community in general. With official recognition, the dental surgeon would not only be himself benefited but would also be in a position in a greater measure to aid in the scientific development of the great healing art, medicine, of which dentistry is a part. The benefits would thus accrue to the medical and dental professions and to the public.

The scientific and practical importance of the close association of the work of the dentist, and especially the operating dentist, with general medicine has long been urged. This fact has been repeatedly stressed by Prof. Oliver T. Osborne of Yale, as may be noted by one of his statements as follows:

"We must recognize, and immediately, that the responsibility of the dentist does not end with the jaws. Also the physician must recognize the relation of the mouth to the general health of the individual and that he must seek consultation with the dental specialist. It is hardly necessary to urge the importance of, or to repeat the proved facts that mouth infection is responsible for a large amount of disease to which civilized races are subject."—*Review of Clinical Stomatology*, June, 1925.

Also, Dr. Lewellys F. Barker of Johns Hopkins University, discussing "The Function of the Dentist," states as follows:

"If medicine has to deal with all varieties of departures of the human organism from health, and if dentistry has to deal with the particular departures of the teeth and the tissues about the teeth from conditions of health, it is obvious that dentistry must be looked upon as a special department of medicine, which became more or less divorced from general medicine mainly on account of the extensive practical-technical manipulations that must be learned for successful practice of dentistry and partly because of the fact that one who specializes in dentistry can have out little time for the practice of general medicine or another medical specialty.

"As a result of the teaching of medicine and of dentistry in separate schools and of the separation of this particular specialty in practice from the other medical specialties and from general medicine and surgery, there was for a long time failure of cooperation between the medical profession as a whole and the dental profession."—March 31, 1930.

Dr. Harlow Brooks of New York University, in an address on "Cooperation Between Physician and Dentist," stated as follows:

"There are very few branches of medicine in which dental problems may not arise, and in which discreet dental judgment is not of value. Signal illustrations of our mutual dependence and of the greater benefit we may give to our clientele by the mutual consideration of clinical prob-

lems are seen notably in reconstructive surgery, particularly of the head, orthopedics, pediatrics, gastro-enterology, and metabolic disorders of all sorts. Even in a field apparently so foreign to dental interests as obstetrics, dental problems appear."

"Irrespective of what you and I may think or wish, I believe it inevitable that in the future dentistry must be considered as a very definite specialty of medicine. There are very many of us who consider that this has already been accomplished in fact, if not in theory."

—*Journal of Dental Research*, December, 1931.

Your petitioners urge that the House of Delegates recommend the formation of a new section under the title of "Section on Stomatology"; or if that does not seem advisable, they would suggest that in a section now established, a subsection be formed entitled "Stomatology."

Application for membership in this section of the American Medical Association should be open to duly graduated licensed dentists holding membership in the American Dental Association.

The activities of the proposed section should be limited to such papers and demonstrations as will permit the growth and scientific value of the medical and surgical aspects of Stomatology. In other words, the problems to be discussed might be outlined as follows:

- (a) Clinical stomatology.
- (b) Stomatologic diagnosis.
- (c) Methods of cooperation between dentist and physician.
- (d) Problems in the fundamental stomatologic sciences such as anatomy, pathology, bacteriology and hygiene.
- (e) Medical and surgical therapy.
- (f) To arrange for the publication of the Transactions of the Section and aid in other ways to enrich stomatologic literature.
- (g) To offer assistance and participate in all such other activities of a scientific and professional nature as it may be called upon to do by the officers of the Association.

Respectfully submitted.

ALFRED J. ASGIS.

The petition was signed by fifty-nine members of the American Medical Association and by twenty-three stomatologists from various parts of the country.

Resolutions Dealing with Listing of Specialists in American Medical Directory

Dr. Samuel J. Kopetzky, New York, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

WHEREAS, The Council on Medical Education and Hospitals for something more than a quarter of a century has been engaged in formulating standards for the training of physicians, and through its policy of investigation and publication has succeeded in elevating the general standard of medical education throughout the country, and

WHEREAS, In recent years the Council has, under the direction of the House of Delegates, in consultation with the leaders in these respective fields, established certain standards for the recognition of qualified physicians specializing in pathology and radiology, and

WHEREAS, There is evidence of a widespread interest in the problems of medical specialism and a very general demand that means be found and standards formulated by which specialists may be known and recognized by their fellows in the profession, and that in this process of standardization there should be a national and uniform standard rather than a multiplicity of standards represented by the various state boards and state societies, and

WHEREAS, A number of special examining boards have already been created to test the fitness and certify the qualifications of men engaged in, or desiring to engage in, special fields of practice, and such certificates have come to be regarded as establishing the skill and proficiency of those to whom they have been issued, and

WHEREAS, The Council may contribute to the usefulness of these special examining boards by granting some form of recognition to those

which now, or hereafter, maintain satisfactory standards of organization and procedure; therefore be it

Resolved, That the Council on Medical Education and Hospitals is hereby authorized to cooperate with the existing examining boards (official) and the Association of American Medical Colleges, the Federation of State Licensing Boards, the National Board of Medical Examiners, through an advisory council hereafter to be set up; and be it further

Resolved, That the trustees and the Council on Medical Education and Hospitals be authorized to deal with the question of listing of specialists in future editions of the American Medical Directory as mutually agreed upon in the advisory council thus set up.

Resolution on Training School in Occupational Therapy

Dr. J. Gurney Taylor, Wisconsin, at the request of the American Occupational Therapy Association, presented the following resolution, which was referred to the Board of Trustees:

WHEREAS, There is a recognized demand for qualified professionally trained occupational therapists in the hospitals of this country, and

WHEREAS, The work of these therapists is under the direction of members of the medical profession, and

WHEREAS, The medical profession and the American Occupational Therapy Association recognize the vital importance of establishing minimum standards of training and the inspection of training schools in occupational therapy by a qualified and authoritative organization; therefore be it

Resolved, That the entire subject be left to the Board of Trustees of the American Medical Association, with the request that it be given careful study and consideration and, if practical and feasible, some plan for the establishment of standards, ratings and inspections of training schools in occupational therapy be effected, providing that the expense of such inspection be borne by the school requesting the same.

Resolution on Radio Broadcasting

Dr. Carl F. Moll, Michigan, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, Radio broadcasting is under the control of the Federal Radio Commission, and

WHEREAS, There are no apparent restrictions of the advertising statements and claims that are being broadcast, and

WHEREAS, The radio is being employed to broadcast unsupportable claims and statements related to a large number of alleged preparations for the cure of many ailments and diseases, thereby misleading the public; therefore, be it

Resolved, That the Board of Trustees through the Bureau of Investigation, and through such other national organizations as the Board may be able to enlist, initiate and pursue activities and efforts to terminate misleading and misrepresenting radio broadcasting that is related to medicinal remedies and preparations for the conservation and protection of the health interests of the public.

Resolutions on Early Election of Delegates

Dr. William H. Myers, Georgia, presented the following resolutions, which were referred to the Reference Committee on Rules and Order of Business:

WHEREAS, The annual sessions of a number of the constituent associations occur so near the time of the annual sessions of the American Medical Association that it is now impossible for them to send in a complete list of the names of their delegates in time for these to appear in the Handbook; be it

Resolved, That the House of Delegates of the American Medical Association respectfully suggests that all constituent associations elect their delegates far enough in advance so that the names of all delegates may be properly listed in the Handbook.

The suggestion is made that the terms of delegates might run from January 1 to December 31 of the years for which they are elected. Be it

Resolved, That a copy of this resolution be sent to the secretaries of all constituent associations.

Resolutions to Broaden Scope of Activities of Council on Medical Education and Hospitals

Dr. Louis J. Hirschman, Michigan, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

WHEREAS, The trend of public events is bringing about readjustments along all avenues of trade, industries, education and social life, and

WHEREAS, Medical education and the practice of medicine is involved in these readjustments, and

WHEREAS, There is a pressing need that factual data be readily available for the information and molding of public opinion and for the guidance of all who seek to establish public policies and public movements, and

WHEREAS, The American Medical Association should exercise a wholesome influence and exhibit an aggressive position in all of these movements to enhance public welfare, and

WHEREAS, Our Council on Medical Education and Hospitals should assume a guiding leadership as it has ever been intended that it should,

and not content itself with routine contact with existent institutions and has not advanced or initiated progressive movements along the avenues of medical education, hospital administration and the public's relation thereto; therefore be it

Resolved, That the Board of Trustees be directed to cause the Council on Medical Education and Hospitals to become aggressively active in:

(a) Evaluating and comparing the merits of the curriculums of approved medical colleges and those alleged colleges operated by the cults.

(b) A study of medical matriculates and graduates for the purpose of determining annual quotas of admission of students.

(c) Devising a course of lectures and demonstrations related to medical ethics, economics, office and practice business details, relationship of physician to patient and public and the fundamental purposes and activities of county, state and national organizations and causing their inclusions in curriculums of approved colleges.

(d) Advisability of accepting a year of association with an approved general practitioner of medicine in lieu of the intern hospital year for all graduates desiring to enter general practice.

(e) A study and devising of a plan that will abolish the so-called state board examinations (often farcical and not at all competent to determine a candidate's qualifications), and in lieu of such examination accept the certification of an approved medical college as to the candidate's training and graduation.

(f) Devising a plan and procedure for the certification of specialists in all branches of medicine and surgery; and be it

Resolved, That the Council on Medical Education and Hospitals impart through effective channels its studies, conclusions and recommendations for the information, advice and guidance of the public and the profession in order that our social readjustments may be influenced by such authentic and dependable information and recommendations.

Resolution on Establishment of a Bureau of Information in Washington, D. C.

Dr. Charles E. Riggs, U. S. Navy, presented the following resolution, which was referred to the Board of Trustees:

WHEREAS, Matters of importance to the welfare of the practitioners of medicine throughout the United States are constantly under consideration and being decided by Congress and other governmental bodies at Washington, D. C., and

WHEREAS, The administrative heads of the four large federal medical groups, viz. those of the Army, Navy, Public Health and Veterans' Administration and, also, the heads of the scientific bureaus of the government are located at Washington, D. C., and

WHEREAS, It is considered desirable that the American Medical Association represent organized medicine in any activities of these legislative, departmental, scientific and other groups in matters affecting the welfare of the practitioners of medicine throughout the country;

Resolved, That the American Medical Association establish and maintain at Washington, D. C., a permanent, properly equipped office with qualified personnel to represent the interests of organized medicine before the committees of Congress, departmental bureaus, scientific societies and other bodies in matters which affect the interests and standing of organized medicine, this department to be under the direction of the Bureau of Legal Medicine and Legislation and to be called, "The Bureau of Information of the American Medical Association."

Resolution on Care of War Veterans

Dr. Charles E. Riggs, U. S. Navy, presented the following resolution, which was presented to the Reference Committee on Legislation and Public Relations:

WHEREAS, For a number of years disabled war veterans have been cared for in hospitals operated by the Veterans' Administration, the Army, Navy, and the Public Health Service, and

WHEREAS, The executive orders and regulations promulgated by the President on March 31 (Reg. No. 10, par. XIX), do not permit the utilization of hospitals of the Army, Navy and Public Health Service, except in an occasional emergency case where the disablement requiring treatment is a result of service, and

WHEREAS, This discontinuance of the use of the hospitals of the regular establishments has already (June 3, 1933) resulted in producing 6,000 unoccupied beds formerly employed for the treatment of war veterans, and

WHEREAS, The high standards of medicine and surgery, the excellent and extensive clinical equipment and the modern structures of the regular services have partially been made possible because of the fact that the war veterans have been assigned to these services for treatment, and

WHEREAS, The diminution in service will make it necessary to surplus much professional and other personnel, thus impairing the efficiency of the hospitals of the regular services, and

WHEREAS, It is manifestly desirable to maintain these hospitals at maximum efficiency so to meet any possible emergencies, and

WHEREAS, Many of the hospitals of the regular services are located so that they are more accessible to veterans than some of the hospitals of the Veterans' Administration; therefore be it

Resolved, By the American Medical Association in national conference assembled that the House of Delegates of the Association request that the Board of Trustees approach the President of the United States, asking his consideration of the proposition of so relaxing the executive orders as to permit the care of service connected war veterans, generally, and those cases requiring hospital treatment, in hospitals of the

regular services, in instances where time, distance, convenience and the nature of the treatment required to be extended so as to wherever possible make use of Army, Navy, or Public Health Service hospitals.

Resolution Limiting Physicians for Hospital Staffs to Members of Association

Dr. G. Henry Mundt, Illinois, presented the following resolution, which was referred to the Reference Committee on Medical Education:

The following resolution was introduced at the 1932 (New Orleans) Session of the American Medical Association. The reference committee in submitting it to the House made the following comment: "The reference committee regards this resolution as an expression of opinion in favor of a standard which should be striven for, and as such approves it, recognizing at the same time that it may not be desirable at present to make it a hard and fast rule." In accordance with that comment I am now requesting the House of Delegates of the American Medical Association to adopt the following resolution:

Resolved, That it is the opinion of the House of Delegates of the American Medical Association that physicians on the staffs of hospitals approved for intern training by the Council on Medical Education and Hospitals should be limited to members in good standing of their local county medical societies and that the House of Delegates request the Council on Medical Education and Hospitals to take this under advisement.

Resolutions on Amount of Clinical Material for Teaching and Research and on Competitive Practice of Medicine

Dr. G. Henry Mundt, Illinois, presented the following resolution, which was referred to the Reference Committee on Medical Education:

At the recent (1933) meeting of the Illinois State Medical Society the following resolution was unanimously adopted and this resolution is presented to ask the concurrence of the House of Delegates of the American Medical Association in the opinion expressed by the House of Delegates of the Illinois State Medical Society.

Resolved, That it is the opinion of the House of Delegates of the Illinois State Medical Society that medical schools should restrict the amount of clinical material used to the amount needed for teaching and research.

Second, That medical schools should not enter into medical practice in competition with private practitioners of medicine.

Third, That the House of Delegates of the Illinois State Medical Society request the House of Delegates of the American Medical Association to request the Council on Medical Education and Hospitals to submit a plan:

- To restrict the amount of clinical material used by medical schools to the amount needed for teaching and research, and
- To restrict the competitive practice of medicine by medical schools.

Resolution Endorsing Minority Report of Committee on the Costs of Medical Care

Dr. Henry C. Macatee, District of Columbia, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The Medical Society of the District of Columbia has endorsed the Minority Report of the Committee on the Costs of Medical Care, and has undertaken to engage in an intensive campaign to educate and inform its constituency regarding the socio-economic aspects of medical practice, with a view to the maintenance of high ethical standards and the preservation of professional ideals:

- By the dissemination of literature;
- By the organization of a speakers' bureau for the purpose of presenting various aspects of the subject to the membership;
- By the organization and conduct of study groups; and
- By the employment of such other means as may from time to time be deemed expedient for that purpose, and

WHEREAS, The Medical Society of the District of Columbia has by resolution instructed its delegate to endeavor to secure the support of the American Medical Association both of the Minority Report of the Committee on the Costs of Medical Care, and of the society's plan for promoting harmony of professional opinion and action on the socio-economic aspects of the practice of medicine;

Resolved, That the House of Delegates of the American Medical Association endorses the Minority Report of the Committee on the Costs of Medical Care as expressive, in principle, of the collective opinion of the medical profession; and, in order to clarify and harmonize the thinking of the individual members of the profession on the general subject of the said report, and on allied subjects.

Resolved, That the Board of Trustees be requested to undertake "the sponsorship, direction and active participation by the American Medical Association in an intensive campaign to be conducted in cooperation with its constituent bodies for the purpose and along the lines indicated" in the first paragraph of the preamble to this resolution.

Resolution on Creation of Committee for Study of Birth Control

Dr. E. D. Plass, Iowa, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The problems and methods of birth control are of vital concern to the health as well as to the social and economic welfare of our American people, and

WHEREAS, The statements of proponents and opponents of birth control are at wide variance, thereby creating confusion and uncertainty, and

WHEREAS, A demand has been made by various groups for dependable evaluation of methods of contraception and of the conditions that justify their employment, and

WHEREAS, These questions are intimately related to medical science and medical practice; therefore be it

Resolved: 1. That this House of Delegates create a special committee of five on "The Study of Contraception" to be appointed by the Speaker, with the advice of the Executive Committee of the Board of Trustees,

2. That this committee is hereby instructed to study the problem of birth control in all its aspects, particularly as they relate to methods of contraception, conditions indicating its employment, and the best manner of imparting instruction to physicians and to the lay public,

3. That this committee be provided by the Council on Pharmacy and Chemistry with a statement of the value and effectiveness of contraceptive products and preparations that are or may be recommended by manufacturers; and be it

Resolved, That the Board of Trustees be requested to instruct the Council on Pharmacy and Chemistry to render all reasonable assistance and advice to this special committee, and to provide this special committee with a fund to be determined after conference with the Committee Chairman, for clerical and correspondence expenses; and be it

Resolved, That the report of this committee, together with all its findings and recommendations, be not disclosed until it has been presented to the 1934 Executive Session of this House of Delegates for consideration and action by this House of Delegates; and be it

Resolved, That the appointment of this special committee shall in no way be construed as an endorsement of birth control on the part of the American Medical Association and that, on the contrary, the appointment of this committee is for the purpose of compiling dependable facts for future guidance when dealing with this question as closely related to public health and medical practice.

Communication Regarding Exploitation of Physicians and Proposed Amendment to By-Laws

Dr. Arthur C. Morgan, Pennsylvania, presented the following communication regarding the exploitation of physicians and proposed an amendment to chapter IX, section 2, of the By-Laws, which was referred to the Reference Committee on Amendments to Constitution and By-Laws:

The singleness of their positions in hospital practice exposes the radiologist and the pathologist to imposition. Many institutions collect and retain their fees, or attempt by taking a percentage of the fees to make a profit from the medical services of these physicians. Those practices constitute exploitation of the physician and are forms of contract practice dangerous to the best interests of the public and the profession.

They are dangerous to the public in that continuance and spread will oblige capable men, because of resentment of exploitation, to avoid entering these fields, and advancement of these two important branches of medicine will be retarded with resultant loss to public welfare. They are dangerous to the medical profession in that they encourage self-seeking interests to exploit other practitioners by the same methods.

While many hospital laboratories are ostensibly under the control of physicians, they are actually controlled by laymen who cause the hospitals to enter into practices and schemes which violate the ethics of the American Medical Association, among them direct solicitation of patients, and the issuance of fee lists and advertising matter.

In view of these facts it is recommended that the Council on Medical Education and Hospitals be instructed to remove annually from their lists of recognized and approved hospitals any institution in which, in the opinion of the county medical society of the county in which the hospital is located, these forms of exploitation are practiced, and from their lists of approved radiologists or approved pathologists any physician who, in the opinion of his county medical society, persists in being a party to these unethical practices.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.
CHARLES F. NASSAU,
President.
FRANKLIN M. CRISPIN,
Executive Secretary.
ARTHUR C. MORGAN.

PROPOSED AMENDMENT TO THE BY-LAWS OF THE AMERICAN MEDICAL ASSOCIATION

It is recommended that chapter IX, section 2, of the By-Laws of the Association be amended to read as follows:

SEC. 2. COUNCIL ON MEDICAL EDUCATION AND HOSPITALS.—The functions of the Council on Medical Education and Hospitals shall be: (1) To investigate conditions of medical education, hospitals and associated subjects and to suggest means and methods by which the

same may be improved. (2) To endeavor to further the realization of such suggestions as may be approved by the House of Delegates. (3) No hospital shall be admitted to the lists of recognized hospitals, and hospitals approved for intern and special training, unless, in addition to meeting the criteria formulated from time to time by the Council it shall also receive annually the approval of the county medical society of the county in which the hospital is located.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

CHARLES F. NASSAU,
President.
FRANKLIN M. CRISPIN,
Executive Secretary.
ARTHUR C. MORGAN.

Resolution on Limiting Number of Medical Graduates

Dr. Arthur J. Bedell, New York, presented the following resolution passed by the house of delegates of the Medical Society of the State of New York, which was referred to the Reference Committee on Medical Education:

Resolved, That the Delegates to the American Medical Association be instructed to ask for a study to be made by the Council on Medical Education and Hospitals of the American Medical Association as to the actual yearly need of medical men for our country, and if it find, from that study, that there are more graduates yearly than are needed, it should use its influence to bring about a limitation of the number of medical matriculants, and hence of medical graduates.

Resolution on Curriculums of Medical Schools

Dr. R. L. Sensenich, Indiana, presented the following resolution, which was referred to the Reference Committee on Medical Education:

Resolved, That it is the opinion of the House of Delegates of the American Medical Association that the curriculum of the medical schools of this country should include some time to be devoted to the training of the student in the basic business procedures necessary successfully to conduct the business of a medical practice.

R. L. SENSENICH,
F. S. CROCKETT,
H. G. HAMER,
D. F. CAMERON.
Delegates
Indiana State Medical Association.

Resolutions on Housing of Army Medical Library and Museum

Dr. Holman Taylor, Texas, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Beginning during the administration of Surgeon General Lovell (1818), the Army Medical Library, also known as the Library of the Surgeon General's Office, has been built up by the Medical Department of the Army at comparatively small cost to the Government, and

WHEREAS, The Army Medical Library, now the largest medical library in the world, has been called, both in Europe and in America, "America's greatest contribution to medicine," and

WHEREAS, As long ago as 1870 a European authority stated that "in five years the United States had done as much in the matter of an anatomical-pathological museum (i. e., the Army Medical Museum), as had been done in all of Europe in a century," since which time the Army Medical Museum has steadily and rapidly grown, its collection today being more than three times as large as at the outbreak of the World War, and

WHEREAS, The important collections of the Army Medical Library and Museum are at present housed in an antiquated building, not fireproof and no longer large enough to contain these institutions, with the result that the work is being hampered, and

WHEREAS, The building occupied by the Army Medical Library and Museum will have to be demolished in accordance with the plans of the Public Buildings Commission for the beautification of Washington already adopted by Congress, and

WHEREAS, The Army Medical Library and Museum serve not only all governmental departments but also the entire medical profession of America and other countries, and without their help much of the research and clinical work now being carried on by our profession would be impracticable, and

WHEREAS, The Public Works Bill now before Congress contemplates the appropriation of the sum of \$3,300,000,000 to erect public buildings and to complete other necessary construction, and likewise to provide employment; therefore be it

Resolved, That the American Medical Association, in annual meeting assembled, respectfully request that the sum of \$2,000,000 be set aside for the purpose of constructing new buildings to house the Army Medical Library and Museum on the site which has already been provided by Congress, and which has now been available for this purpose for more than fourteen years, namely, adjacent to the Army Medical School and the Walter Reed General Hospital at the Army Medical Center, Washington, D. C.; and be it further

Resolved, That copies of these resolutions be sent to the President of the United States, the President of the Senate, the Speaker of the House of Representatives, the chairman of the Appropriations Committee of the Senate, the chairman of the Appropriations Committee of the House of

Representatives, the chairman of the Military Affairs Committee of the Senate, the Chairman of the Military Affairs Committee of the House, and to the Secretary of War.

Communication from the Department of Vital Statistics

Dr. Olin West, Secretary, presented a communication from the chief statistician of Vital Statistics of the Bureau of the Census, which was referred to the Reference Committee on Hygiene and Public Health.

Resolution Requesting National Medical Organizations to Declare Opinions on Medical Practice Through Approved Channels

Dr. Olin West, Secretary, presented a resolution that was adopted by the Council of the State Medical Society of Wisconsin, which is similar to a resolution from the Medical Society of the State of Pennsylvania that was presented to the House earlier. This resolution was referred to the Reference Committee on Rules and Order of Business.

Resolutions Dealing with the Foreign Political Situation

The Speaker referred to the Reference Committee on Legislation and Public Relations, without reading, two resolutions dealing with the foreign political situation that were mailed to the Secretary.

The meeting adjourned at 12:55 p. m., to reconvene at 9:30 Tuesday morning, June 13.

Second Meeting—Tuesday Morning, June 13

The House of Delegates was called to order at 9:30 a. m. by the Speaker, Dr. F. C. Warnshuis.

Dr. E. G. Wood, Tennessee, moved that the attendance slips constitute the roll call of the House. The motion was seconded by Dr. C. S. Gorsline, Michigan, and carried.

On motion of Dr. Arthur J. Bedell, New York, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, the House dispensed with the reading of the minutes.

Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, reported irregularities, mostly due to lost cards, all coming under the rules under which the committee operates, and recommended that the following named gentlemen be seated: Drs. George Blumer, Connecticut; C. W. Hibbitt, Kentucky; Charles E. Mongan, Massachusetts; Felix J. Underwood, Mississippi; B. R. McClellan, Ohio; J. Norman Henry, and S. P. Mengel, Pennsylvania; J. J. Crume, Texas; George H. Scott, U. S. Army; Stanley H. Osborn, Section on Preventive and Industrial Medicine and Public Health, and H. W. E. Walther, Section on Urology. He added that there were 159 registrations.

There being no objections, the Speaker stated that the supplementary report of the committee would be received and placed on file.

Dr. Brook also reported that since Dr. W. T. Rainey, North Carolina, is not a Fellow of the American Medical Association and, under section 1, chapter I, of the By-Laws, is not eligible to a seat in this House, the committee recommended that he be not seated.

Dr. H. A. Luce, Michigan, supported the recommendation, which was carried by vote of the House, and Dr. Rainey was not seated.

Report of Council on Scientific Assembly

Dr. John Edward Lane, Chairman, presented the following report, which was adopted on motion of Dr. Lane, seconded by Dr. H. B. Everett, Tennessee, and carried:

A communication from Dr. Alfred J. Asgis, director of the American Society of Stomatologists, requesting the formation of a Section on Stomatology, has been referred to the Council on Scientific Assembly by the House of Delegates.

There was formerly a Section on Stomatology in the American Medical Association. Largely because of small attendance and difficulty in arranging programs, this section was discontinued some years ago.

After due consideration the Council on Scientific Assembly feels that it would, at present, be unwise to reestablish this section or, as requested by Dr. Asgis, to establish a subsection in one of the already existing sections. The medical aspects of stomatology, as they relate to the various specialties of medicine, may be presented appropriately in the respective sections.

The Council on Scientific Assembly therefore recommends to the House of Delegates that a Section on Stomatology be not established.

Respectfully submitted.

JOHN E. LANE, Chairman.
IRVIN ABELL.
FRANK H. LAHEY.
ROGER MORRIS.
FRANK SMITHIES.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following report:

The Judicial Council recommends to the House of Delegates that the name of Dr. H. D. Pease of New York be dropped from the roll of members of the American Medical Association because of unethical conduct.

On motion of Dr. Follansbee, seconded by Dr. Arthur J. Bedell, New York, and carried, the report was adopted.

Report of Board of Trustees

Dr. J. H. J. Upham, for the Board of Trustees, presented the following report:

1. Relative to the resolution introduced by Dr. Charles E. Riggs, the Board expresses the belief that the recently established permanent representative in Washington and the provision for suitable appearance before representative bodies by members of the staff of the Bureau of Legal Medicine and Legislation, as well as by members of the Committee on Legislative Activities, will accomplish all that is contemplated in this resolution. The Board has not yet had opportunity to prove that anything more is necessary; therefore it does not recommend the adoption of the resolution introduced by Dr. Riggs.

2. Concerning the resolution on occupational therapy, introduced by Dr. J. Gurney Taylor, Wisconsin, the Board recommends that this resolution be referred to the Council on Physical Therapy and the Council on Medical Education and Hospitals for consideration and investigation.

Dr. Louis J. Hirschman, Michigan, moved the adoption of the first section of the report, which was seconded by Dr. C. B. Wright, Minnesota, and carried.

On motion of Dr. C. S. Gorsline, Michigan, seconded by Dr. H. B. Everett, Tennessee, and carried, the second section of the report was adopted.

The report of the Board of Trustees was then adopted as a whole.

Report of Reference Committee on Hygiene and Public Health

Dr. W. F. Draper, Chairman, presented the following report:

1. The Reference Committee on Hygiene and Public Health recommends the adoption of the resolution in regard to activities and efforts to terminate misleading and misrepresenting radio broadcasting, relating to medicinal remedies and preparations for the conservation and protection of the health interests of the public.

2. The Reference Committee on Hygiene and Public Health recommends the adoption of that part of the report of the Board of Trustees which deals with the Bureau of Health and Public Instruction.

3. The Reference Committee on Hygiene and Public Health recommends the indorsement by the House of Delegates of the American Medical Association of the work of the Division of Vital Statistics of the Federal Bureau of the Census. It recommends further that the members of the Association interest themselves in the valuable work of the Division of Vital Statistics as related to the medical profession, and that they render their assistance either as members of county, state or other organizations, or as individuals.

Dr. Draper moved that the first section of the report be adopted, and the motion was seconded by Dr. C. W. Roberts,

Georgia. On suggestion of Dr. Holman Taylor, Texas, the resolution referred to in this section of the report was amended to read as follows:

WHEREAS, Radio broadcasting is under the control of the Federal Radio Commission, and

WHEREAS, There appear to be no apparent restrictions of the advertising statements and claims that are being broadcast, and

WHEREAS, It appears that the radio is being employed to broadcast unsupported claims and statements related to a large number of alleged preparations for the cure of many ailments and diseases, thereby misleading the public; therefore be it

Resolved, That the Board of Trustees, through the Bureau of Investigation, and through such other national organizations as the Board may be able to enlist, initiate and pursue activities and efforts to terminate misleading and misrepresenting radio broadcasting that is related to medicinal remedies and preparations for the conservation and protection of the health interests of the public.

The first section of the report was adopted, with the resolution as amended, after discussion by Dr. George Blumcr, Connecticut.

It was moved by Dr. Draper, seconded by Dr. Felix J. Underwood, Mississippi, and carried, that the second section of the report be adopted.

On motion of Dr. Draper, seconded by Dr. Joseph F. Smith, Wisconsin, and carried, the third section of the report was adopted.

Dr. Draper moved the adoption of the report as a whole. The motion was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Holman Taylor, Chairman, presented the following report:

1. A resolution by Dr. Southgate Leigh, delegate of the Medical Society of Virginia, provides that presidents of constituent state medical associations shall be ex officio members of the House of Delegates. Reference to the matter will be found on page 35 of the Handbook in the report of the Secretary.

Your committee recommends that the words "without the right of vote" be added to the amendment immediately following the words "shall be ex officio members."

Your committee warmly approves of the purpose underlying the proposed amendment, which is, in short, that a very definite and direct connection between the American Medical Association and its constituent state associations be thus effected, but it is felt that should such an amendment to the Constitution be adopted, the net results would be a greater confusion of tongues than exists at the present time; in other words, that the added discussion, from even very able members, who must speak without authority, would help little and doubtless prolong discussion unduly. We recommend that the amendment do not pass.

2. The following amendment to chapter IX, section 2, of the By-Laws of the Association, introduced by Dr. Arthur C. Morgan at the instance of the Philadelphia County Medical Society, has been before your committee:

SEC. 2. COUNCIL ON MEDICAL EDUCATION AND HOSPITALS.—The functions of the Council on Medical Education and Hospitals shall be: (1) To investigate conditions of medical education, hospitals and associated subjects and to suggest means and methods by which same may be improved. (2) To endeavor to further the realization of such suggestions as may be approved by the House of Delegates. (3) No hospital shall be admitted to the lists of recognized hospitals, and hospitals approved for intern and special training, unless, in addition to meeting the criteria formulated from time to time by the Council it shall also receive annually the approval of the county medical society of the county in which the hospital is located.

Your committee is of the opinion that the added provision would tend to confuse and complicate a situation already sufficiently difficult, and that the matter of listing hospitals of whatsoever type or character had better remain as at present, wholly in the hands of the Council on Medical Education and Hospitals, which council, as we understand it, now takes into consideration the opinion of county medical societies and their members, when such opinion may be obtained. We recommend that the amendment be not passed.

3. The question having been raised before our committee, we take the liberty of suggesting to the House of Delegates that the Board of Trustees may help to bring constituent state associations into closer touch and more direct contact with the

American Medical Association by sending representatives of the American Medical Association to states which have not requested the favor, as well as into states which have asked for such help.

Respectfully submitted.

HOLMAN TAYLOR, Chairman.
BEN R. MCCLELLAN.
JAMES R. BLOSS.
E. L. SKIDMORE.
J. M. BIRNIE.

Dr. Taylor moved that the amendment to the amendment, proposed in the second paragraph of the first section of the report be adopted. The motion was seconded by Dr. H. H. Shoulders, Tennessee. After discussion by Drs. H. H. Shoulders, Tennessee, Holman Taylor, Texas, and B. F. Bailey, Nebraska, Dr. Mather Pfeifferberger, Illinois, moved that the motion be tabled. The motion to table was seconded by Dr. R. W. Fouts, Nebraska, and carried, after the Speaker ruled that the tabling also included the amendment proposed by the reference committee.

Dr. Horace Reed, Oklahoma, moved the adoption of the recommendation of the committee contained in the third paragraph of the first section of the report. The motion was seconded by Dr. A. A. Ross, Texas, and carried.

Dr. Taylor moved that the recommendation of the committee contained in the second section of the report be adopted. Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, seconded the motion, which was carried.

The third section of the report was adopted on motion of Dr. Taylor, seconded by Dr. Southgate Leigh, Virginia, and carried, after which the report was adopted as a whole, with the exception of that part that had been tabled.

Report of Reference Committee on Reports of Officers

Dr. F. S. Crockett, Chairman, presented the following report:

1. Your committee wishes to commend the masterful address of our President. The work which he has done and the principles which he enumerates are so thoroughly in accord with the best thoughts of organized medicine that we urge a perusal of this splendid document by each member of the Association when it appears in our official organ. He reviewed the year's accomplishments, calling attention to the successful issues attained: (1) the right of the physician to use his own judgment in prescribing alcoholic liquors; (2) the defeat of Sheppard-Townerism and the substitution of state and local agencies for federal bureaucracy; (3) the steps taken in further control of narcotics through uniform state legislation; (4) the activities of the legislative committee in regard to veterans' care, which, without doubt, exerted marked influence in the recent executive orders affecting the hospitalization of cases having no service origin; (5) endorsing the Minority Report of the Committee on the Costs of Medical Care and calling attention to the soundness of the principles enunciated; (6) the need for unity of spirit and professional desire in our county and state societies as a necessary corollary to successful action through our national Association.

2. Your committee endorses the views of the President-Elect in his interpretations of the attitude the medical profession should take in regard to the care of the veterans. To this end we would call attention to his suggestion that, after all, the personal contact of the doctor with his representative in the legislature is one of the most vital factors in influencing legislation along this line. The President-Elect has well touched on the cost of medical care and emphasized an important phase sometimes overlooked in the high cost of hospital construction, which greatly increases the cost without increased benefits to the patient. Your committee also commends his attitude against questionable forms of insurance for the care of the sick. He likewise admirably states his conviction that merging of hospitals in many communities would lead to better service to all parties concerned. He deals with the limitation of specialism and the simplification of medical practice, which we believe should provide for a more satisfactory relationship of medical practice in the light of changes now in progress, especially in medical education.

3. Your committee would stress the caution as given to this House of Delegates by the Speaker in considering resolutions about to be presented and urge that it is to be remembered

that we are a confederation of many minds, and as doctors work under varying conditions, so that new resolutions and changes should be only those enumerating principles which are to maintain for long periods of time. For his usual genial, kindly and strict, yet impartial, guidance in our deliberations, as a presiding officer, your committee feels that this Association has been particularly fortunate.

4. Your reference committee approves the report of the Judicial Council and recommends its adoption as read. Dr. Edwin P. Sloan, a member of the Judicial Council, appeared before the committee and suggested the following additions to that part of the report concerning contract practice, as follows:

I wish to propose that the second paragraph of the proposed addition to the section on contract practice in the report of the Judicial Council be changed as follows:

Following the word "unethical" at the end of the first sentence of that paragraph insert:

"Under some conditions adequate service can be provided only by contract practice and is essential for the public welfare."

Following the word "patients" at the end of the sentence indicated by (6) insert:

"(7) When his professional services are controlled or exploited by any intermediary agency, personal or corporate, which intervenes between physician and patient."

Your committee recommends that these additions be referred to the Judicial Council for its study and consideration.

Dr. Crockett moved the adoption of the first section of the report dealing with the address of the President. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried.

On motion of Dr. Crockett, seconded by Dr. W. F. Braasch, Minnesota, and carried, the second section of the report, referring to the address of the President-Elect, was adopted.

With Dr. E. H. Cary, President, in the chair, it was moved by Dr. Crockett, seconded by Dr. Horace Reed, Oklahoma, and carried, that the third section of the report dealing with the address of the Speaker be adopted.

The recommendations contained in the fourth section of the report, which refer to the report of the Judicial Council, were adopted on motion of Dr. Crockett, seconded by Dr. G. Henry Mundt, Illinois, and carried, and the report of the reference committee was then adopted as a whole.

Remarks of Dr. George H. Simmons

The Speaker presented Dr. George H. Simmons, Editor and General Manager Emeritus, who spoke as follows:

Mr. Speaker, you know perfectly well that I can't make a speech, that I hate to hear myself talk. You persist in ignoring me in that.

It certainly is a pleasure to me to meet pretty nearly every year with the House of Delegates. As you know, I was at its birth, saw the struggle at that first meeting at Saratoga Springs. How many are present who were there? [Four.] It was a sorry hour for about an hour, but soon after that everything went smoothly, and, so far as I know, it has been going smoothly ever since.

I notice year by year problems coming up—the same old problems that you have to look at from a different angle because social conditions are changing, political conditions are changing, and we are changing. But I notice as these problems are met and solved—or laid on the table—we still make progress up.

I can't express to you what I feel with regard to this House of Delegates as being a body of men selected to represent the medical profession of the whole country, and how much depends on your action. Probably you all realize it as much as I do, and I have no suggestions of criticism, nothing of the kind, but it is a responsibility that you gentlemen are holding, and especially in these times. I have no doubt the problems as they come up will be solved satisfactorily to us, and as the president of the State Medical Society of Wisconsin said last night, "Onward, forward!"

Report of Reference Committee on Reports of Board of Trustees and Secretary.

Dr. Nathan B. Van Etten, Chairman, presented the following report:

Your Reference Committee on Reports of Board of Trustees and Secretary notes with regret a net loss of members and Fellows but believes that general economic conditions must be charged with the chief responsibility and that reestablishment

of normal conditions and a renewed interest in the value of medical organization will soon bring the membership and Fellowship up to higher numbers than before.

Your reference committee views with satisfaction the increased interest in the field work of the Association as shown in the increasing number of requests for official visits, heartily commends the remarkable response to these requests by the President, the President-Elect, Trustees, Secretary, Editor and the other administrative personnel, and believing that this work will be increasingly necessary for the cohesion and development of our component elements, your reference committee recommends the consideration by the Board of Trustees of the advisability of the appointment of a Field Secretary to meet the growing demand for interpretation of the Association to the membership, the activity of such an appointee in no way to interfere with the invaluable work of the present Bureau of Medical Economics.

Your reference committee highly commends the increasingly valuable and tactful service of the Secretary and General Manager and wishes him many years of continued success.

Your reference committee congratulates the Board of Trustees on the remarkable success of the investment committee's selection of securities resulting in the maintenance of so high a return on invested capital, and the general conduct of the finances of the Association with such discriminating economy that the fluid solvency of the Association has been at all times maintained.

Your reference committee applauds the successful issue of the defense of the suit brought against the Association by Baker of Muscatine, Iowa.

Your reference committee observes with regret the loss of \$32,875 through the publication of the special journals and recommends to the Trustees either temporary curtailment or raising the subscription price of these journals in order to reduce this deficiency.

Your reference committee notes with satisfaction the inclusion of the discussion of economics in so impartial and impersonal a manner in *THE JOURNAL*, approves the maintenance of the high quality of *THE JOURNAL* at so low a subscription price, and recommends the continuation of the present general policy.

Your reference committee laments the financial burden of the *QUARTERLY CUMULATIVE INDEX* but believes that its value to scientific medicine is so great that its publication should be maintained.

Your reference committee applauds the success of *HYGEIA*.

Your reference committee approves of the action of the Trustees in the publication of the Directory.

Your reference committee approves of the extension of the Library and hopes for its continued growth and ultimately competent and dignified housing.

Your reference committee approves of the action of the Trustees in the continuation of their emergency policy relating to Fellowships and subscriptions.

Your reference committee commends the Council on Pharmacy and Chemistry and the Chemical Laboratory and urges a continuation of the maintenance of their high standards of honesty and excellence.

Your reference committee commends the action of the Council on Physical Therapy and recommends the spread of education concerning the values and the dangers attending the employment of physical therapy apparatus by untrained people, and the control of deceptive advertising and high pressure salesmanship.

Your reference committee believes that the Bureau of Investigation is highly valuable and that its work should be continued and extended.

Your reference committee heartily commends the Bureau of Exhibits and congratulates it on the marvelous development of its scientific and educational presentations.

Your reference committee believes that the work of the Committee on Foods is being carried on with exceptional fidelity to insistence on honest advertising and promotion of public welfare.

The report of the reference committee, on motions duly seconded and carried, was adopted section by section and, on motion of Dr. Van Etten, seconded by Dr. Arthur J. Bedell, New York, and carried, the report was adopted as a whole.

Report of Reference Committee on Miscellaneous Business

Dr. H. M. Johnson, Chairman, presented the following report:

Your committee would recommend that the Board of Trustees of the American Medical Association be requested to take the necessary steps to carry out the fulfillment of the resolution introduced by Dr. Holman Taylor, Texas, and referred to this committee.

H. M. JOHNSON, Chairman.
A. R. McCOMAS.
B. L. BRYANT.
J. F. HASSIG.
GEORGE BLUMER.

On motion of Dr. Johnson, seconded by Dr. Louis J. Hirschman, Michigan, and carried, the report was adopted.

Report of Reference Committee on Rules and Order of Business

Dr. John F. Hagerty, Chairman, presented the following report:

1. The committee endorses the resolutions that constituent associations elect their delegates far enough in advance so that the names of all delegates may be properly listed in the Handbook of the House of Delegates, and approves of the suggestion, where possible, that the terms of delegates run from January 1 to December 31 of the years for which they are elected. It also endorses the suggestion that copies of this resolution be sent to the secretaries of all constituent associations.

2. The committee also endorses the resolutions presented by the board of trustees of the Medical Society of the State of Pennsylvania and the council of the State Medical Society of Wisconsin, which are practically identical and which declare that all public opinions on general, social, legislative and economic relationships of medical practice be made only through approved channels of the American Medical Association.

Respectfully submitted. JOHN F. HAGERTY, Chairman.

Dr. Hagerty moved the adoption of the first section of the report with respect to the election of delegates by constituent associations and the motion was seconded by Dr. William H. Myers, Georgia. The resolutions were referred back to the committee after discussion by the Secretary.

On motion of Dr. Hagerty, seconded by Dr. William R. Molony, California, and carried, the second section of the report, endorsing the resolutions declaring that all public opinions on general social, legislative and economic relationships of medical practice be made only through approved channels of the American Medical Association, was adopted.

Remarks of Dr. Hubert Work

The Speaker presented Dr. Hubert Work who addressed the House as follows:

Mr. Speaker, I thank you cordially for this opportunity to look the House of Delegates in the face again. I once occupied the position your Speaker does and I spent many a happy and many an anxious hour before this House of Delegates.

Mr. Speaker, if the temper of the House is as it used to be, when they always appraised a speech by the brevity of it, I just simply want to say to you hail and farewell.

Report of Reference Committee on Medical Education

Dr. Irvin Abell, Chairman, presented the following report:

The report of the Council on Medical Education and Hospitals displays a comprehensive grasp of the problems presented in these fields and the employment of constructive efforts to advance their solution. The resolution embodied in paragraph 2 of the report reading, "Resolved, That should the House of Delegates so order, the Council is prepared to extend to other special fields of medicine the service which it has rendered in the fields of radiology and pathology to the end that members of the medical profession and others who may be concerned may be able readily to distinguish those who have received training in the various branches of medicine from those who are merely self-constituted 'specialists,'" is recommended for adoption.

It is recommended that the handbook entitled Hospital Practice for Interns, listed as one of the publications of the Council, be adopted by the hospitals on the approved list and that such institutions place copies at the disposal of the interns.

The Council is to be commended for its initiative in securing adoption by the Federation of State Medical Boards of the United States of the resolutions pertaining to the matriculation of American students in European schools and to the admission of American graduates of such schools to state medical licensing examinations to the end that migration of less desirable students might be in a measure restrained.

The paragraph in the report of the Council dealing with hospital activities reveals the large extent of the work done in this field. The fact that 241 hospitals have been dropped from the register shows the fidelity with which standards are maintained, while the program for the current year indicates an extension of comprehensive investigation.

The report shows the large amount of worth-while work done in the classification of pathologists and radiologists, 1,725 physicians having been classified in the two groups. In view of the classification of specialists heretofore authorized, it is suggested by the Reference Committee that examining boards for these specialties be created whose standards will in degree approximate those for the remaining specialties.

The supplement dealing with Essentials of an Acceptable Medical School, with its Appendix, is recommended for adoption.

The supplement dealing with Essentials in a Hospital Approved for Residencies in Specialties is recommended for adoption.

The report of the Committee on Mental Health reveals a painstaking and intelligent study of the subject and its perusal is recommended to every member of the House of Delegates for his information. The Reference Committee concurs fully in the summary projected by the Committee on Mental Health but would differ from it in its recommendations. The establishment of a bureau or committee of mental health, composed of physicians with special training and experience in the field of mental health, while theoretically desirable, is, under existing conditions, somewhat impracticable, both because of the expense entailed and because of the duplication of efforts which may be effectually dispensed by other bureaus. For these reasons the Reference Committee recommends that the subdivisions of work suggested by the Committee on Mental Health be carried on under the supervision of the Board of Trustees through the following channels: (1) "psychiatry in relation to medical education and hospitals" through the Council on Medical Education and Hospitals; (2) "public policies and procedures in mental health administration" through the Bureau of Legal Medicine and Legislation; (3) "research in mental health" and (4) "dissemination of information" through the Bureau of Health and Public Instruction.

The resolution passed by the house of delegates of the Medical Society of the State of New York, April 3, 1933, presented by Dr. Bedell, requests a study by the Council on Medical Education and Hospitals as to the actual yearly need of medical men for our country and, in the event of finding the present supply excessive, the use of its influence in bringing about a limitation. The reference committee recommends that no action be taken, since the subject matter of this resolution is fully covered in paragraph 12 of the Report of the Council on Medical Education and Hospitals.

The resolution of the delegates of the Indiana State Medical Association, introduced by Dr. Sensenich, in which the opinion of the House of Delegates is expressed that the curriculum of the medical schools of this country should include some time to be devoted to the training of the student in the basic business procedures necessary to conduct successfully the business of a medical practice, is recommended for adoption.

The resolution of the Illinois State Medical Society, introduced by Dr. G. H. Mundt, requests the House of Delegates of the American Medical Association to request the Council on Medical Education and Hospitals to submit a plan (a) to restrict the amount of clinical material used by medical schools to the amount needed for teaching and research and (b) to restrict the competitive practice by schools of medicine. The widely differing conditions that exist in various parts of our

country are such that it does not seem feasible to the Reference Committee to adopt uniform regulations that would be equitable to all parties concerned. The competitive practice of medical schools, particularly so far as it relates to pay patients, is to be discouraged and condemned. Since the Council on Medical Education and Hospitals is conversant with the conditions which exist in all parts of the country, the Reference Committee recommends that the resolution be referred to it without action for its consideration.

A resolution introduced by Dr. G. H. Mundt defines the opinion of the House of Delegates to be that physicians on the staffs of hospitals approved for intern training by the Council on Medical Education and Hospitals should be limited to members in good standing of their local county medical societies and that the House of Delegates request the Council on Medical Education and Hospitals to take this under advisement. Paragraph 5 of the report of the Council states that, as a result of the introduction of this resolution last year, a study of 110 institutions with 9,933 physicians on their respective staffs showed 66.4 per cent to be Fellows and 20.6 per cent members of the American Medical Association. The Reference Committee finds itself in harmony with the comment made last year on this resolution by the then reference committee; namely, "It regards this resolution as an expression of opinion in favor of a standard which should be striven for, and as such approves it, recognizing at the same time that it may not be desirable at present to make it a hard and fast rule."

Resolutions introduced by Dr. Hirschman of Michigan suggest activities on medical education and hospitals as follows:

Resolved, That the Board of Trustees be directed to cause the Council on Medical Education and Hospitals to become aggressively active in:

(a) Evaluating and comparing the merits of the curriculums of approved medical colleges and those alleged colleges operated by the cults.

This information is on file and available at the office of the Council.

(b) A study of medical matriculates and graduates for the purpose of determining annual quotas of admission of students.

This information is also available at the office of the Council, much of it being quoted in paragraph 12 of the 1933 report.

(c) Devising a course of lectures and demonstrations related to medical ethics, economics, office and practice business details, relationship of physician to patient and public and the fundamental purposes and activities of county, state and national organizations and causing their inclusion in curriculums of approved colleges.

The subject matter of this section is partly covered in the recommendation contained in the resolution introduced by Dr. Sensenich of the Indiana delegation; the remainder is referred with approval of the Reference Committee to the Council on Medical Education and Hospitals.

(d) Advisability of accepting a year of association with an approved general practitioner of medicine in lieu of the intern hospital year for all graduates desiring to enter general practice.

The Reference Committee disapproves of this section and recommends that it be not adopted.

(e) A study and devising of a plan that will abolish the so-called state board examination (often farcical and not at all competent to determine a candidate's qualifications), and in lieu of such examination accept a certification of an approved medical college as to the candidate's training and graduation.

The Reference Committee recommends that this be referred without comment to the Council on Medical Education and Hospitals.

(f) Devising a plan and procedure for the certification of specialists in all branches of medicine and surgery.

This section is fully covered by the resolution embodied in paragraph 2 of the report of the Council.

Be it further

Resolved, That the Council on Medical Education and Hospitals impart through effective channels its studies, conclusions and recommendations for the information, advice and guidance of the public and the profession in order that our social readjustments may be influenced by such authentic and dependable information and recommendations.

The Reference Committee recommends that the activities mentioned in this paragraph be discharged by the Bureau of Health and Public Instruction.

A resolution introduced by Dr. Samuel J. Kopetzky of New York pertains to the adoption of a national and uniform standard by which specialists may be known and recognized by their fellows in the profession. Dr. Kopetzky's resolution was fully and freely discussed in the committee by Dr. Fishbein representing the Board of Trustees, by the members of the Council on Medical Education and Hospitals, and by the representatives of the examining boards of the special societies. As a result of this conference the Reference Committee recommends for adoption the following resolution as an amendment to that introduced by Dr. Kopetzky:

WHEREAS, The Council on Medical Education and Hospitals for something more than a quarter of a century has been engaged in formulating standards for the training of physicians, and through its policy of investigation and publication has succeeded in elevating the general standard of medical education throughout the country, and

WHEREAS, In recent years the Council has, under the direction of the House of Delegates, in consultation with the leaders in these respective fields, established certain standards for the recognition of qualified physicians specializing in pathology and radiology, and

WHEREAS, There is evidence of a widespread interest in the problems of medical specialism and a very general demand that means be found and standards formulated by which specialists may be known and recognized by their fellows in the profession, and that in this process of standardization there should be a national and uniform standard rather than a multiplicity of standards represented by the various state boards and state societies, and

WHEREAS, A number of special examining boards, the American Board of Ophthalmic Examinations, the American Board of Otolaryngology, the American Board of Obstetrics and Gynecology and the American Board of Dermatology and Syphilology, have been created to test the fitness and certify the qualifications of men engaged in, or desiring to engage in, special fields of practice, and such certificates have come to be regarded as establishing the skill and proficiency of those to whom they have been issued, and

WHEREAS, The Council may contribute to the usefulness of these special examining boards by granting some form of recognition to those which now, or hereafter, maintain satisfactory standards of organization and procedure; therefore be it

Resolved, That the Council on Medical Education and Hospitals is hereby authorized to express its approval of such special examining boards as conform to the standards of administration formulated by the Council; and be it further

Resolved, That the Board of Trustees of the American Medical Association be urged to use the machinery of the American Medical Association, including the publication of its Directory, in furthering the work of such examining boards as may be accredited by the Council.

IRVIN ABELL, Chairman.
E. D. PLASS.
W. H. ROSS.
S. P. MENGEL.
MATHER PFEIFFENBERGER.

On motions, duly seconded and carried, each section of the report was adopted. Dr. Abell moved that the report be adopted as a whole. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried.

Report of Reference Committee on Medical Economics

Dr. Arthur J. Bedell, Chairman, presented the following report:

Mr. Speaker and Members of the House of Delegates:

Your committee has carefully reviewed the report as published in the Handbook and concurs with the Bureau that "the problems that presented themselves were not all the result of current social and economic conditions but were, in some instances, the culmination of long standing and gradually developing practices. The schemes which were promulgated in the guise of cures for certain alleged faults in the administration of medical service represent a rapid extension of commercialism into the provision of medical services."

Your committee appreciates the special consideration that has been given to contract practice and agrees that this type of medical work is constantly changing. It recommends that the study of contract practice be continued, and the action of county societies in dealing with these problems be based on the recommendations of the Judicial Council:

By the term "contract practice," as applied to medicine, is meant the carrying out of an agreement between a physician or a group of physicians as principals or agents and a corporation, organization or individual, to furnish partial or full medical services to a group or class of individuals for a definite sum or for a fixed rate per capita.

Contract practice per se is not unethical. However, certain features or conditions if present make a contract unethical, among which are:

(1) When there is a solicitation of patients, directly or indirectly. (2) When there is underbidding to secure contracts. (3) When the compensation is inadequate to assure good medical service. (4) When there is interference with reasonable competition in a community. (5) When free choice of a physician is prevented. (6) When the conditions of his employment make it impossible to render adequate service to his patients. (7) When the contract because of any of its provisions or practical results is contrary to sound public policy.

Each contract should be considered on its own merits and in the light of surrounding conditions. Judgment should not be obscured by immediate, temporary or local results. The decision as to its ethical or unethical nature must be based on the ultimate effect, for good or ill, on the people as a whole.

Group hospitalization has been described and criticized in several issues of THE JOURNAL. Certain phases of some plans may have merit. The committee believes many contain features which are subversive to the best interest of the public, the medical profession and the hospital, and it condemns any plan which incorporates principles contrary to the remarks on contract practice. The committee recommends that the investigation of group hospitalization be continued and that the results of the studies be published in the Medical Economics department of THE JOURNAL.

The provisions of most workmen's compensation laws have been a constant source of irritation and annoyance to employees, employers and the medical profession. The committee approves of the report, prepared by the Bureau, on Medical Relations under Workmen's Compensation and recommends that it form the basis of state conferences.

The committee looks with favor on the medical economics course in medical colleges but urges that only competent instructors be employed. It recommends that the outline on medical economics be completed by the Bureau and submitted to all medical schools who desire it.

Group practice has received widespread attention. The articles in THE JOURNAL have been comprehensive in scope and the facts presented well correlated and so authentic that they should form the basis for any consideration of the problem and be read by all members of the Association. Those forming a group should be guided by the same principles regarding professional qualifications for practice, ethical relations to fellow practitioners and consideration for the economic position of those whom they serve as should guide the individual practitioner.

The committee notes the conferences on health and accident insurance practice and recommends the approval of the proposed short form health and accident claim proof blanks. It senses in this newly developed relation between our Association and this service group opportunities for improvement in our mutual contacts.

The committee commends the Bureau's activities, the field investigations of the director and his assistant, the number of special engagements that have been filled and particularly the published analyses. All of these efforts have been excellent and command attention and the committee recommends that they be continued.

It is with a feeling of pride and a growing sense of security based on the information gathered and disseminated by this Bureau that the committee recommends the report as a whole to the House of Delegates and expresses its approval of the work done by the director and his assistant.

ARTHUR J. BEDELL, Chairman.
WALTER F. DONALDSON.
C. W. WAGGONER.
JABEZ N. JACKSON.

The various sections of the report were adopted on motions of Dr. Bedell, duly seconded and carried, after discussion by Dr. Holman Taylor, Texas, and by the Secretary, after which the report of the committee was adopted as a whole.

Report of Reference Committee on Legislation and Public Relations

Dr. C. E. Mongan, Chairman, presented the following report:

1. With reference to the resolution introduced by Dr. Henry C. Macatee, delegate from the Medical Society of the District of Columbia, your committee recommends that the House of Delegates commend the action of the Medical Society of the

District of Columbia in informing its members of the medical and social implications of the Minority Report of the Committee on the Costs of Medical Care, in order to enable them better to support the principles and recommendations of that report. Your committee recommends that the House of Delegates commend this plan to the favorable consideration of other constituent associations.

Your committee believes that the organization of groups around hospitals or otherwise, supported by a voluntary or compulsory insurance or taxation, as recommended by the Majority Report of the Committee on Costs of Medical Care, would be inimical to the best interests of all concerned. It believes that such a plan, if compulsory, would encourage malingerers, would create a vast political machine with all its evils, would inevitably lead to state medicine, and would reduce our profession to the status of government employees with the present relation of physician and patient a thing of the past. Your committee believes the Minority Report and its recommendations offer the best solution of the existing situation and the only hope for a future stabilized medical practice. It recommends that the House of Delegates adopt the resolution proposed by Dr. Macatee, namely:

Resolved, That the House of Delegates of the American Medical Association endorse the Minority Report of the Committee on the Costs of Medical Care as expressive, in principle, of the collective opinion of the medical profession.

2. Your committee recommends that the House of Delegates approve the principle suggested in the resolution offered by Admiral C. E. Riggs, U. S. Navy, namely, that veterans suffering from service-connected disabilities be treated in the hospitals of the Army, Navy and Public Health Service, instead of in the hospitals of the Veterans' Administration, whenever it is to the best interests of the disabled veteran that he be so treated. Your committee recommends further that the Auxiliary Committee on Veterans' Affairs be authorized to do, under the direction of the Board of Trustees, whatever may be possible to carry this principle into effect, so far as is consistent with effective and economical government administration.

3. Your committee commends the work of the Committee on Legislative Activities and of its Auxiliary Committee on Veterans' Affairs. It recommends that the committee and its auxiliary committee use every effort to discover, through our constituent state associations and otherwise, the extent, if any, to which veterans who are denied medical and hospital care under the order recently issued by the President are in need of such care but unable to obtain it through local medical and hospital services in the communities in which they reside.

Your committee recommends that the House of Delegates adopt a resolution endorsing the policy of the President to reduce the cost of medical and surgical care of veterans to rational proportions, equitable both to the veteran and to the taxpayer, and pledging the Association to support that policy.

Your committee recommends that the attention of our several state associations be called to the recommendation of the Committee on Legislative Activities, urging action to prevent the practice of medicine by corporations. The illegality of the practice of medicine by corporations has been established by the decisions of a number of state supreme courts.

Your committee wishes to bring to the notice of the House of Delegates the comment by the Committee of Legislative Activities; namely, "We call attention to the excellent work that is being done by the Bureau of Legal Medicine and Legislation. Exact information is always available through this Bureau on legal aspects of the practice of medicine, and on legislative activities, both state and national. A brief résumé of the activities of this Bureau was published in the April number of the AMERICAN MEDICAL ASSOCIATION BULLETIN."

Your committee heartily approves this comment.

4. Your committee offers the following resolutions for adoption:

Resolved, That the American Medical Association commends the efforts of the President to preserve to all veterans suffering from service-connected disabilities all medical and hospital benefits necessary to their relief; and

Resolved, That the Association commends, too, the action of the President looking toward a reduction in medical and hospital benefits for veterans who are without service-connected disabilities, so that the cost of

the benefits provided, if any, will be reasonable, and equitable to the taxpayer as well as to the veteran; and further

Resolved, That copies of these resolutions be sent immediately to the President, the Vice President, the Speaker of the House of Representatives, the Director of the Budget and the Director of the Veterans' Administration.

5. Your committee concurs in the recommendation of the Board of Trustees contained in the report of the Bureau of Legal Medicine and Legislation that proper narcotic legislation by each of the several states be urged. Your committee recommends that the Association approve the draft of the proposed uniform state act concerning the control of narcotic drugs, prepared by the National Conference of Commissioners on Uniform State Laws and approved by the American Bar Association. This draft had its origin in the work of a committee of the American Medical Association, and in its preparation the Bureau of Legal Medicine and Legislation had an active part.

Your committee concurs in the recommendation that the House of Delegates approve the draft of a proposed uniform medical lien law, prepared by the Bureau of Legal Medicine and Legislation and submitted to the several state associations as a guide in the preparation of similar legislation.

CHARLES E. MONGAN, Chairman.

CHARLES J. WHALEN.

WELLS TEACHNOR, SR.

E. M. PALLETTE.

A. A. ROSS, Secretary.

On motions of Dr. Mongan, duly seconded and carried, the first three sections of the report were adopted.

Dr. Mongan moved that the resolutions contained in section 4 of the report be adopted. The motion was seconded by Dr. Charles H. Goodrich, New York, and carried, after the Secretary had been instructed to convey this message in the form of a telegram to the President.

Section 5 of the report was adopted on motion of Dr. Mongan, duly seconded and carried.

Dr. Mongan moved the adoption of the report as a whole. The motion was seconded by Dr. Mather Pfeifferberger, Illinois, and carried.

UNFINISHED BUSINESS

Preliminary Report on Hospitalization of the Mentally Ill in the United States

The Secretary presented the preliminary report of the Council on Medical Education and Hospitals on the Hospitalization of the Mentally Ill in the United States, which had been prepared by the Council with the assistance of an advisory committee in accordance with instructions received from the House of Delegates a year or two ago. The printed report was referred to the Reference Committee on Medical Education.

Cablegram from Secretary of British Medical Association

The Secretary read a cablegram received from the Secretary of the British Medical Association:

"Council of the British Medical Association regrets inability to appoint delegate, but sends fraternal greetings and best wishes for successful annual session. ANDERSON, Secretary, British Medical Association."

NEW BUSINESS

Resolutions on Use of Term "Economics of Medical Services"

Dr. Charles H. Goodrich, New York, presented the following resolutions, which were referred to the Reference Committee on Medical Economics:

WHEREAS, The term "medical economics" is not only misleading to the practitioner and the public but is also an incomplete expression of the economic cognations of medicine and surgery, and

WHEREAS, The public is inclined to infer that we are considering only the financial advantages to physicians because we use the term "medical economics" as an appellation for the Bureau or for committees, and

WHEREAS, The economics of medical service concerns all of the people and their community and governmental organizations; be it

Resolved, That in all of the literature, addresses and discussions of the American Medical Association the term "economics of medical services" replace the term "medical economics"; and be it

Resolved, That in naming the Bureau and special committees the unmodified term "Economics" be used (as "Bureau of Economics").

Resolution on Annual Observance of a State Health Day

Dr. Walter F. Donaldson, Pennsylvania, with the support of the entire Pennsylvania delegation, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The triumphs of preventive medicine over the diseases of childhood and early adult life have resulted in the development of enormously increased age groups at 50 years and beyond, and

WHEREAS, The prevention and treatment of diseases peculiar to the advanced age groups involves more on the individual medical practitioner than on health departments, and

WHEREAS, Public interest in the prevention of the degenerative diseases of the advanced age groups is woefully lacking; therefore be it

Resolved, That the House of Delegates of the American Medical Association urge on the constituent state associations the annual observance of a State Health Day, to be marked throughout each county of each state by the coordinating leadership of the component medical society.

Report of Public Health Committee of Medical Society of New Jersey

Dr. B. S. Pollak, New Jersey, presented a report of the Public Health Committee of the Medical Society of New Jersey, which was referred to the Reference Committee on Hygiene and Public Health.

Resolution on Advertising Foods Over the Radio

Dr. George Blumer, Connecticut, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The advertising of food of various types over the radio has been subject to extraordinary exaggerations and misleading statements likely to be harmful to the public health; therefore be it

Resolved, That the Board of Trustees, in its action opposing harmful advertising of drugs over the radio, include also a consideration of the control of the advertising of foods.

Remarks of Dr. T. C. Routley

The Speaker presented Dr. T. C. Routley, secretary of the Canadian Medical Association, who addressed the House as follows:

Mr. Chairman, Mr. President and Gentlemen:

Arriving here last night, I have been very busy from that hour until now. I can't help but think of the homely philosophy of the Chinaman. This Chinaman spent two years in this great country and then returned to his own home, and there obtaining a position on the docks, he was very much delighted one day to see a gentleman, obviously from the United States, standing on the dock looking at the longshoremen at work.

He said as he passed this American, "Come buy cargo?" The American shook his head no.

Then as he passed him a second time, he said, "Come, look and see?" The American shook his head no.

As he passed him the third time, he said, "Well, there only one more class. A man either come buy cargo, come, look and see, or he expect to die soon." (Laughter.)

I do want to say this, Mr. Chairman and gentlemen, that so far as your great country and this Association are concerned, I belong to the second class. I have come to look and see, and for ten years I have been doing this to my own great delight.

I bring you most cordial greetings from your colleagues in medicine in Canada. The president has desired me to say to you that you will all be welcome in Canada any time you care to come and honor us with a visit.

I am looking forward with great pleasure to renewing old friendships here and making some new ones. I do thank you most cordially for the kindly way in which you have received me.

Proposed Amendment to By-Laws

Dr. D. E. Sullivan, New Hampshire, presented the following amendment to chapter XI, section 2, of the By-Laws, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

Amend chapter XI, section 2, by adding after the word *subscription* in the last line of paragraph 2, the following: Physicians who are employed by the United States government as full time physicians in service other than commissioned officers of the United States Army, U. S. Navy and U. S. Public Health Service, shall be Fellows while so employed by the government, provided such physicians subscribe to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

The House recessed at 11:15 a. m. to reconvene at 1:15 p. m.

Tuesday Afternoon, June 13

The House of Delegates was called to order at 1:15 p. m. by the Speaker, Dr. F. C. Warnshuis.

Report of the Reference Committee on Medical Education

Dr. Irvin Abell, Chairman, read the following supplementary report of the Reference Committee on Medical Education:

The preliminary report of the Council on Medical Education and Hospitals on the Hospitalization of the Mentally Ill in the United States shows a rather extensive study of 631 hospitals and institutions concerned in the care and treatment of the mentally ill. Your reference committee recommends the acceptance and filing of the Preliminary Report and that the House of Delegates express its appreciation and thanks both to the Council and to the Committee, which has worked so faithfully with it.

The seriousness and importance of the problem of the mental disordered and defectives, and the mental health of the country, is such that your reference committee recommends a continuation of the study under its present setup to the end that a complete report may be presented at the next annual session of the House of Delegates.

IRVIN ABELL, Chairman.
E. D. PLASS.
W. H. ROSS.
S. P. MENGEL.
MATHER PFEIFFENBERGER.

On motion of Dr. Abell, seconded by several members of the House, and carried, the report was adopted.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Holman Taylor, Chairman, presented the following report:

The following amendment to the By-Laws of the Association, introduced by Dr. D. E. Sullivan of New Hampshire, has been submitted to your committee:

Amend chapter XI, section 2, by adding after the word *subscription* in the last line of paragraph 2, the following: Physicians who are employed by the United States government as full time physicians in service other than commissioned officers of the United States Army, United States Navy and U. S. Public Health Service, shall be Fellows while so employed by the government, provided such physicians subscribe to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

The evident purpose of the proposed amendment is to place the several medical services of the federal government not heretofore so recognized on a par with medical officers of the United States Army, United States Navy and United States Public Health Service. Your committee is of the opinion that the exceptions originally made in favor of the services mentioned were made because of certain exigencies of those services which do not obtain in the case of the services for which exemption is now being sought. It can see no good reason why physicians employed in these additional services may not become members of component county medical societies and assume their proportionate share of the burdens and responsibilities involved in the practice of medicine. Some exceptions might well be made in the interest of these physicians, were it practicable to make them, but that problem is not before your committee. Your committee recommends that the amendment do not pass.

Respectfully submitted.

HOLMAN TAYLOR, Chairman.
BEN R. McCLELLAN.
JAMES R. BLOSS.
E. L. SKIDMORE.
J. M. BIRNIE.

The report was adopted on motion of Dr. Taylor, seconded by several members of the House, and carried.

Report of Reference Committee on Rules and Order of Business

Dr. John F. Hagerty, Chairman, presented the following report:

At a later meeting of the Reference Committee on Rules and Order of Business, it was decided to withdraw the latter half of the resolution concerning election of delegates.

SCHOOL OF NURSING MILWAUKEE SESSION HARBORVIEW DIVISION.

JOUR. A. M. A.
JULY 1, 1933

The resolution as approved, now reads: The committee endorses the resolution that constituent associations elect their delegates far enough in advance so that the names of all delegates may be properly listed in the Handbook of the House of Delegates and requests that copies of this resolution be sent to the secretaries of all constituent associations.

JOHN F. HAGERTY, Chairman.

Dr. Hagerty moved that the report be adopted. The motion was seconded by Dr. William H. Myers, Georgia, and carried.

Executive Session—Tuesday Afternoon, June 13

The Speaker declared the House in executive session.

Report of Reference Committee on Legislation and Public Relations

Dr. Charles E. Mongan, Chairman, presented the following report:

With reference to the question submitted to your committee on the subject of the persecution of Jewish physicians in Germany, your committee begs leave to submit the following resolution:

Resolved, That the American Medical Association in annual session assembled condemns the persecution of any individual on account of race or religion by any state or under any flag.

CHARLES E. MONGAN, Chairman.

On motion of Dr. Mongan, seconded by Dr. William R. Molony, California, and carried, the resolution was adopted.

Report of Reference Committee on Hygiene and Public Health

Dr. W. F. Draper, Chairman, after reading resolutions introduced by Dr. E. D. Plass, Iowa, and referred to the Reference Committee on Hygiene and Public Health, relating to birth control, presented the following report:

Your committee is of the opinion that it is proper and desirable that the House of Delegates should have in its possession full and accurate knowledge and information in regard to the subject of birth control, which may be used for guidance in such future action as it may wish to consider. The committee, therefore, recommends the adoption of the resolutions.

W. F. DRAPER, Chairman.

J. GURNEY TAYLOR.

GRANT C. MADILL.

J. NORMAN HENRY.

W. ALBERT COOK.

Dr. Draper moved that the report be adopted, and the motion was seconded by Dr. Walter Ralph Steiner, Connecticut.

After discussion by Dr. Edward M. Pallette, California, Dr. Pallette moved that the motion be laid on the table. The motion to table was seconded by Dr. D. E. Sullivan, New Hampshire, and several other members of the House, and carried by a vote of 66 in favor and 46 opposed.

Presentation of Dr. E. Starr Judd

The Speaker presented Dr. E. Starr Judd, a Past President, who greeted the members of the House.

Dr. Austin A. Hayden, Treasurer, stated for the Local Committee on Arrangements that there would be seats reserved and held for the members of the House of Delegates and the officers of the Association at the Opening General Meeting.

The House recessed at 1:50 p. m., to meet at 1 o'clock Thursday afternoon, June 15.

Third Meeting—Thursday Afternoon, June 15

The House of Delegates was called to order at 1 p. m. by the Speaker, Dr. F. C. Warnshuis, who announced that the House of Delegates would adjourn from executive session into regular session.

Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, reported that 162 delegates, who had presented proper credentials, were registered; and that the committee had received, just a few moments before, credentials in the form of a telegram from the president of the Mississippi

State Medical Association, stating that Dr. Paul Gamble was the regular alternate for his brother, Dr. H. A. Gamble.

Dr. Brook moved that Dr. Paul Gamble be seated. The motion was seconded by Dr. C. S. Gorsline, Michigan, and carried, and the Speaker announced that the House had adopted the report of the Reference Committee on Credentials.

On motion of Dr. H. H. Shoulders, Tennessee, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, the House dispensed with the reading of the minutes.

Report of Reference Committee on Medical Economics

Dr. Arthur J. Bedell, Chairman, presented the following report, which was adopted on motion of Dr. Bedell, duly seconded and carried:

Your committee has received the resolution introduced by Dr. Goodrich. In the judgment of the committee, this proposed change would institute so many alterations in the existing setup in component and constituent societies, as well as in this organization, that we recommend the continuance of the present term.

ARTHUR J. BEDELL, Chairman.

JABEZ N. JACKSON.

C. W. WAGGONER.

WALTER F. DONALDSON.

Report of Reference Committee on Hygiene and Public Health

Dr. W. F. Draper, Chairman, presented the following report:

1. Your committee has noted with interest and appreciation the report of the Public Health Committee of the Medical Society of New Jersey and recommends that this report be filed with the Bureau of Health and Public Instruction.

2. Your committee approves the inclusion of foods in the resolution already adopted in regard to the radio advertising of medicinal preparations and the like, and so recommends.

3. While your committee is in an entire accord with the desirability of creating public interest in the degenerative diseases of the advanced age group, it is of the opinion that in view of the endorsement previously recorded by the Association of the periodic health examination and because of the multiplicity of present-day observations already in effect the designation of a State Health Day as contemplated in the resolution would not be of particular advantage. Your committee therefore recommends that the resolution be not adopted.

W. F. DRAPER, Chairman.

J. GURNEY TAYLOR.

J. NORMAN HENRY.

GRANT C. MADILL.

The report of the reference committee was adopted section by section on motions by Dr. Draper, duly seconded and carried, and was adopted as a whole on motion of Dr. Draper, seconded by Dr. Mather Pfeifferberger, Illinois, and carried.

Resolutions on Psychiatric Service in the Administration of Criminal Justice

Dr. T. B. Throckmorton, Section on Nervous and Mental Diseases, presented the following resolutions, which were adopted on motion of Dr. Throckmorton, seconded by Dr. Felix J. Underwood, Mississippi, and carried:

WHEREAS, A knowledge of prevailing methods of providing psychiatric service for courts and other agencies having to do with crime and criminals is essential to the establishment of an adequate psychiatric service on an efficient basis;

Resolved, That the American Medical Association recognizes the desirability of a survey of prevailing methods by which psychiatric service is now provided for courts and other agencies dealing with crime and of the results of such methods; and further

Resolved, That the Association urges its constituent and component societies to devote at least one meeting annually, to which members of the local bar associations shall be invited, for the joint discussion of psychiatric service in the administration of criminal justice and the treatment of the offender.

Resolution on Prevention of Blindness by Examination of Pregnant Women

Dr. Edward Stieren, Section on Ophthalmology, presented the following resolution:

WHEREAS, Prenatal syphilis is responsible for interstitial keratitis and for many uveal and neural changes resulting in defective sight and blindness as well as deafness and other defects, and

WHEREAS, It has been found that above 3 per cent of the women attending prenatal clinics—in certain studies as high as 30 per cent—have shown a positive reaction to the Wassermann test, and it has been estimated on the basis of group studies that from 3 to 5 per cent of children taken in the mass have prenatal syphilis and that about half of these children without adequate treatment develop interstitial keratitis leading to defective vision if not blindness, and

WHEREAS, It has been authoritatively stated that prenatal syphilis can, without doubt, be prevented in the majority of cases, but only if there is complete cooperation between the patient and the various medical, social and educational agencies which enter into the diagnosis, the treatment and the care of the infected pregnant woman, and if treated adequately in the child before organic changes have occurred, it is curable without loss of sight, and

WHEREAS, This deplorable condition can be controlled only by combined efforts of the medical, the social and public health authorities; therefore be it

Resolved, That the Section on Ophthalmology requests the House of Delegates of the American Medical Association to appoint a committee to take this subject under advisement and to arrange methods by which cooperation may be secured through the combined efforts of the American Medical Association, the National Society for the Prevention of Blindness, the American Social Hygiene Association, the obstetric and ophthalmologic societies, the American Dermatological Association, public health organizations and such other organizations as can help, in order that blood examinations may be made of all pregnant women so that methods may be arranged for the treatment of all those infected with syphilis, thereby preventing the blindness and other tragedies which would otherwise inevitably follow.

Dr. Stieren moved that the resolution be adopted. The motion was seconded by Drs. Emily D. Barringer, New York, and G. Henry Mundt, Illinois, and carried, after Dr. Frank W. Gregor, Section on Dermatology and Syphilology, had stated that a similar, identical resolution was unanimously adopted by that section.

Message of Sympathy and Best Wishes to Dr. William H. Welch

Dr. Grant C. Madill, New York, moved that the Secretary be requested to extend by telegram a message of sympathy and best wishes for the recovery of Dr. William H. Welch, Baltimore, who is ill. The motion was seconded by several members of the House and carried.

Report of Reference Committee on Credentials

On request of the Speaker, the Secretary called the roll.

Dr. J. D. Brook, Chairman of the Reference Committee on Credentials, stated that neither Dr. Charles E. Kiely, delegate from Ohio, nor Dr. Louis H. Schriyer, his alternate, was in attendance but that Dr. G. F. Zinninger, alternate for Dr. John P. DeWitt, was present and desired to be seated for Dr. Kiely.

Dr. Mather Pfeifferberger, Illinois, moved that Dr. Zinninger be seated. The motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried.

ELECTION OF OFFICERS

'Election of President-Elect

On request of the Speaker, the Secretary read section 1, chapter IV of the By-Laws.

Dr. William H. Mayer, Pennsylvania, nominated, for President-Elect, Dr. Edward B. Heckel, Pittsburgh, and the nomination was seconded by Dr. Arthur J. Bedell, New York.

Dr. R. I. Lee, Massachusetts, nominated Dr. Harvey Cushing, Boston, and the nomination was seconded by Dr. Walter Ralph Steiner, Connecticut.

Dr. Fred Moore, Iowa, nominated Dr. Walter L. Bierring, Des Moines, Iowa. The nomination was seconded by Dr. G. Henry Mundt, Illinois, and Dr. T. B. Throckmorton, Section on Nervous and Mental Diseases.

The Speaker declared the nominations closed, and appointed as tellers Dr. G. Henry Mundt, Illinois; Dr. Frank P. Lytle, Pennsylvania; Dr. Thomas F. Thornton, Iowa; Dr. H. B. Everett, Tennessee, and Dr. Fred B. Clarke, California.

The Secretary, at the request of the Speaker, announced that 158 delegates had been recorded as present, and that 157 votes had been cast, of which Dr. E. B. Heckel, Pittsburgh, received 42; Dr. Harvey Cushing, Boston, 41, and Dr. Walter L. Bierring, Des Moines, Iowa, 74.

The Speaker declared that none of the candidates having received the required majority of votes, the lowest candidate

would be eliminated and it would be necessary to take a second ballot.

The Secretary announced as the result of the second ballot that 155 votes had been cast, of which Dr. E. B. Heckel, Pittsburgh, received 48 and Dr. Walter L. Bierring, Des Moines, Iowa, 107.

The Speaker declared Dr. Walter L. Bierring, having received the majority of votes cast, elected President-Elect of the American Medical Association.

On motion of Dr. William H. Mayer, Pennsylvania, duly seconded and carried, the election of Dr. Walter L. Bierring was made unanimous.

Election of Vice President

Dr. Joseph F. Smith, Wisconsin, nominated, for Vice President, Dr. John H. Musser, New Orleans. The nomination was seconded by Dr. Carl F. Moll, Michigan; Dr. Felix J. Underwood, Mississippi; Dr. H. W. E. Walther, Section on Urology, and Dr. J. Q. Graves, Louisiana.

Dr. William H. Seemann, Louisiana, moved that the nominations be closed. The motion was seconded by Dr. Lyell C. Kinney, California, and carried.

Dr. William H. Seemann, Louisiana, moved that the Secretary cast the ballot of the House for Dr. John H. Musser as Vice President. The motion was seconded by Dr. Felix J. Underwood, Mississippi, and carried, and the Secretary cast the unanimous ballot of the House for Dr. John H. Musser, New Orleans, for Vice President.

The Speaker declared Dr. John H. Musser elected as Vice President of the American Medical Association for the ensuing year.

Election of Secretary

Dr. Louis J. Hirschman, Michigan, nominated, for Secretary, Dr. Olin West, Chicago. Dr. C. S. Gorsline, Michigan, moved that nominations be closed, and the motion was seconded by Dr. Albert Soiland, Section on Radiology, and carried.

On motion of Dr. Arthur J. Bedell, New York, seconded by Dr. H. B. Everett, Tennessee, and carried, the Speaker cast the unanimous ballot of the House for Dr. Olin West as Secretary of the American Medical Association and declared Dr. West elected Secretary for the ensuing year.

Election of Treasurer

Dr. J. H. J. Upham, for the Board of Trustees, nominated, for the office of Treasurer, Dr. Herman L. Kretschmer, Chicago.

Dr. H. W. E. Walther, Section on Urology, moved that the nominations be closed. The motion was seconded by Dr. Crum Epler, Colorado, and carried.

Dr. Mather Pfeifferberger, Illinois, moved that the Secretary cast the ballot of the House for Dr. Herman L. Kretschmer, Chicago, as Treasurer. The motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, and the Secretary cast the vote of the House for Dr. Herman L. Kretschmer, Chicago, as Treasurer of the Association.

The Speaker declared Dr. Herman L. Kretschmer elected as Treasurer of the American Medical Association for the ensuing year.

Election of Speaker of the House of Delegates

Dr. E. H. Cary, a Past President, took the chair and announced that the next order of business was the election of a Speaker of the House of Delegates.

Dr. J. D. Brook, Michigan, nominated, for Speaker of the House of Delegates, Dr. F. C. Warnshuis, Grand Rapids, Mich. The nomination was seconded by Drs. H. H. Shoulders and H. B. Everett, Tennessee, and by several other members of the House. Dr. Albert Soiland, Section on Radiology, moved that the nominations be closed. The motion was seconded by several members and carried.

On motion of Dr. Mather Pfeifferberger, Illinois, duly seconded and carried, the Secretary cast the unanimous vote of the House for Dr. F. C. Warnshuis to serve as Speaker of the House of Delegates, and Dr. Cary declared Dr. F. C. Warnshuis duly elected Speaker of the House of Delegates for the ensuing year.

Address of President-Elect Walter L. Bierring

The Speaker resumed the chair and introduced President-Elect Walter L. Bierring, who addressed the House as follows:

Mr. Speaker, Members of the House of Delegates:

This is one of the times when the words will not come forth that we would like to say. Somehow I feel that you have undertaken a good deal of responsibility in your action today.

As we reflect on the more than thirty years that this House of Delegates has been in organization there comes the thought that we are all servants and devotees of a common cause and we seem as one in our devotion to our great organization in which there seems to be but little place for individual distinction. When one thinks of what has been accomplished since you have been organized there is a common feeling of pride—the evolution of medical training that has been the marvel of the educational world, the supervision of pharmacologic products and therapeutic procedures, the unity of methods of medical practice, the conservative recognition of specialized forms of practice, the development of a scientific assembly and a marvelous exhibit of preeminent educational value, all expressed to the medical world through the medium of a great journal that has been under the fortunate guidance of a great editor for more than a quarter of a century, and much we owe to that Nestor of medical journalism, Dr. George H. Simmons, and likewise to that genius and leader in medical thought, the distinguished editor of today, Dr. Morris Fishbein, who has done so much for medical journalism in this new work and carried it far afield.

You have been an exhibit of rare judgment again in that you have considered these many forms in this changing order, social and economic, and still kept the middle road, and somehow you have instilled in all of us a confidence that in the future as in the past you are capable of keeping your own house in order.

I cannot tell you how much I am touched by your confidence, but if I may express myself it is only to give my fullest pledge of all that is in me for your service, and in all humility I thank you.

Election of Vice Speaker of the House of Delegates

Dr. Frederic E. Sondern, New York, nominated, for Vice Speaker of the House of Delegates, Dr. Nathan B. Van Etten, New York. The nomination was seconded by Dr. E. R. Mulford, New Jersey; Dr. William G. Ricker, Vermont, and Dr. J. Newton Hunsberger, Pennsylvania, after which on motion of Dr. B. F. Bailey, Nebraska, duly seconded and carried, the nominations were closed.

On motion of Dr. Arthur J. Bedell, New York, duly seconded and carried, the Secretary cast the vote of the House for Dr. N. B. Van Etten, New York, as Vice Speaker of the House of Delegates, and the Speaker declared Dr. Van Etten elected Vice Speaker of the House of Delegates for the ensuing year.

Election of Trustees

The Speaker declared the next order of business to be the election of a trustee for a term of five years to succeed Dr. J. H. Walsh, Chicago, whose term expired this year and who, according to the By-Laws, was not eligible for reelection.

Dr. Mather Pfeifferberger, Illinois, nominated Dr. Charles B. Reed, Chicago, and the nomination was seconded by Dr. Fred Moore, Iowa.

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, nominated Dr. Austin A. Hayden, Chicago, and the nomination was seconded by Dr. Samuel J. Kopetzky, New York.

The Speaker declared the nominations closed and requested the Secretary to announce the result of the ballot.

The Secretary stated that 154 votes had been cast, of which Dr. Charles B. Reed received 71 and Dr. Austin A. Hayden, 83.

The Speaker declared Dr. Austin A. Hayden, Chicago, having received the majority vote of the House, elected as a trustee of the American Medical Association for a term of five years.

On motion of Dr. C. B. Reed, Illinois, seconded by Dr. Samuel J. Kopetzky, New York, and carried, the election of Dr. Hayden was made unanimous.

The Speaker called for nominations for the office of Trustee to succeed Dr. A. R. Mitchell, deceased, whose term of office had expired.

Dr. W. F. Braasch, Minnesota, nominated Dr. C. B. Wright, Minneapolis. The nomination was seconded by Dr. H. H.

Shoulders, Tennessee; Dr. F. S. Crockett, Indiana, and Dr. William R. Malony, California.

Dr. McLain Rogers, Oklahoma, nominated Dr. W. Albert Cook, Oklahoma, and the nomination was seconded by Dr. Crum Epler, Colorado.

Dr. Jabez N. Jackson, Missouri, nominated Dr. Emmett P. North, St. Louis. The nomination was seconded by Dr. R. W. Fouts, Nebraska, and Dr. Warren F. Draper, Virginia.

The Speaker declared the nominations closed and the Secretary announced that 153 votes had been cast, of which Dr. C. B. Wright received 85; Dr. W. Albert Cook, 33, and Dr. Emmett P. North, 35.

The Speaker declared that Dr. C. B. Wright, having received the majority vote of the House of Delegates, had been elected as a member of the Board of Trustees for a term of five years.

On motion of Dr. McLain Rogers, Oklahoma, seconded by Dr. Jabez N. Jackson, Missouri, and carried, the election of Dr. Wright was made unanimous.

Nominations for Standing Committees

The Secretary, at the request of the President, read the following nominations of the President for Standing Committees:

Dr. J. H. O'Shea, Spokane, Wash., to succeed Dr. Frank W. Cregor on the Judicial Council for a term of five years.

Dr. James S. McLester, Birmingham, Ala., to succeed himself as a member of the Council on Medical Education and Hospitals for a term of seven years.

Dr. James E. Paullin, Atlanta, Ga., to succeed Dr. Roger S. Morris on the Council on Scientific Assembly for a term of five years.

On motion of Dr. Charles E. Humiston, Illinois, seconded by Dr. G. Henry Mundt, Illinois, and by Dr. H. B. Everett, Tennessee, and carried, the nominations were confirmed.

Election of Affiliate and Associate Fellows

The Secretary read nominations for Affiliate and Associate Fellowship:

APPLICANTS FOR AFFILIATE FELLOWSHIP APPROVED BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

Campbell, M. G., Atlanta, Ga.
Hammond, J. H., LaFayette, Ga.
Carson, Andros, Des Moines, Iowa.
Harris, F. R., Henderson, N. C.
Richards, B. U., Pawtucket, R. I.
Black, Thomas F., Providence, R. I.
Farrell, John T., Providence, R. I.
Munro, Walter L., Providence, R. I.
White, William R., Providence, R. I.
Burk, F. Edward, Wakefield, R. I.
Nay, W. Scott, Underhill, Vt.
Grim, A. S., St. Marys, W. Va.
Guttery, W. V., Middletown, Ill.
Black, H. R., Spartanburg, S. C.
Stribling, J. S., Seneca, S. C.
Crafts, Leo M., Minneapolis.
Reiter, Henry W., Shakopee, Minn.
Mott, John S., Kansas City, Mo.
Newlon, C. S., Kansas City, Mo.
Burrill, C. W., Kansas City, Mo.
Cordier, A. H., Kansas City, Mo.
Kanoky, J. P., Kansas City, Mo.
Crawford, H. S., Kansas City, Mo.
Pearson, Charles L., Newton, Mass.
Chisman, E. P. H., Boston.

APPLICATIONS FOR ASSOCIATE FELLOWSHIP FROM AMERICAN MEDICAL MISSIONARIES APPROVED BY THE JUDICIAL COUNCIL

Bowles, Herbert E., Tokyo, Japan.
Brines, Rolland James, Lowanho, Yencheng, China.
Brownsberger, Sidney B., Bobbili, Madras Presidency, India.
Gribble, Florence N., Yaloke, French Equatorial Africa.
Jensen, Jacob R., Monrovia, Liberia, West Africa.
Veatch, Everett P., Nana Kru, Liberia, West Africa.
Wagner, Grace St.C., Taiku, Shansi, China.

APPLICANTS FOR ASSOCIATE FELLOWSHIP NOMINATED BY THE SECTIONS INDICATED**SURGERY, GENERAL AND ABDOMINAL**

Brunschwig, Alexander, Chicago.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

Asgis, A. J., New York.
Cronauer, Charles, Jr., Englewood, N. J.
Ericsson, J. Oliver, Norristown, Pa.
Gassen, Nathan M., New York.
Hayes, Louis V., New York.

PHARMACOLOGY AND THERAPEUTICS

Crittenden, Phoebe J., Washington, D. C.
Lamson, Paul D., Nashville, Tenn.

PATHOLOGY AND PHYSIOLOGY

Eyster, John A. E., Madison, Wis.
Koser, Stewart A., Chicago.
Long, Esmond R., Philadelphia.
Menkin, Valy, Boston.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

Herring, Robert A., Washington, D. C.
Soper, George A., Great Neck, N. Y.

Dr. Arthur J. Bedell, New York, moved that the applicants listed be elected to Affiliate or Associate Fellowship in the American Medical Association, as indicated. The motion was seconded by Dr. Mather Pfeifferberger, Illinois, and carried, and the Speaker declared the applicants elected.

Nomination for Honorary Fellowship

Dr. Arthur H. Curtis, Section on Obstetrics, Gynecology and Abdominal Surgery, nominated for Honorary Fellowship Dr. Reuben Peterson of Ann Arbor, Mich. The nomination was referred to the Council on Scientific Assembly, after discussion by the Speaker; Dr. Holman Taylor, Texas; the Secretary; Dr. Louis J. Hirschman, Michigan, and Dr. Curtis.

Place of the 1934 Annual Session

The Speaker announced that the next order of business was the selection of the place of the 1934 annual session and requested the Board of Trustees to present nominations.

Dr. J. H. J. Upham, for the Board of Trustees, stated that consideration had been given by the Board of Trustees to the facilities of the cities from which invitations had been received for the 1934 meeting of the Association; i. e., Long Beach, Calif.; Atlantic City, N. J.; Baltimore, Md.; Pasadena, Calif.; Cleveland, Ohio, and Washington, D. C., and that the Board had to report that Atlantic City and Cleveland have the most satisfactory facilities for accommodating a meeting of the Association.

Dr. Henry C. Macatee, District of Columbia, nominated Washington, D. C., and extended an invitation from that city. Dr. Walt P. Conaway, New Jersey, extended an invitation from Atlantic City, and Dr. C. W. Stone, Ohio, an invitation from Cleveland.

The Speaker declared the nominations closed, and the Secretary announced that 144 votes had been cast, of which Atlantic City had received 33; Cleveland, 96; Washington, 14, and Milwaukee, 1.

The Speaker declared Cleveland the place for the next annual session of the American Medical Association, as it had received a majority of the votes cast.

Report of Council on Scientific Assembly

Dr. John E. Lane, Chairman, stated that the name of Dr. Reuben Peterson had been submitted to the Council for approval for election as an Honorary Fellow. The Council recommended the election.

Dr. Louis J. Hirschman, Michigan, moved that the recommendation of the Council be adopted. The motion was seconded and carried.

Dr. Arthur H. Curtis, Section on Obstetrics, Gynecology and Abdominal Surgery, moved that Dr. Reuben Peterson be elected as an Honorary Fellow. The motion was seconded by Dr. Louis J. Hirschman, Michigan, and by Dr. E. D. Plass, Iowa, and carried, and the Speaker declared Dr. Peterson so elected.

Unfinished Business

Dr. J. Newton Hunsberger, Pennsylvania, moved that a vote of thanks be extended to the Medical Society of Milwaukee County, the State Medical Society of Wisconsin, the Auxiliary, the press, and the citizens of Milwaukee for their hospitality during the session, adding that they had given very delightful weather also. The motion was seconded by Dr. Arthur J. Bedell, New York, and carried unanimously.

The House of Delegates adjourned sine die at 3:40 p. m.

REGISTRATION AT MILWAUKEE

The total registration at the Milwaukee session was 4,601. Below are given two summaries—one by sections and one by states:

Association News

ABSTRACT OF MINUTES OF MEETINGS
OF BOARD OF TRUSTEES HELD
JUNE 11-16, 1933

The first meeting of the Board of Trustees during the week of the Milwaukee Session of the Association was held at Dr. Rock Sleyster's home at Wauwatosa, Wis., on Sunday, June 11; other meetings were held at the Schroeder Hotel in Milwaukee on ensuing days during the session.

A resolution expressing the Board's appreciation of the loyal, constructive and understanding efforts of Dr. Albert R. Mitchell in behalf of the physicians of the United States and its sense of personal loss in his death was adopted for presentation to the House of Delegates, and a personal communication was prepared and sent to his widow.

ADDITIONAL ASSISTANT FOR COUNCIL ON
PHARMACY AND CHEMISTRY

The employment of an additional assistant for the Council on Pharmacy and Chemistry was authorized, with a view to having more of the preliminary work of the Council handled in the headquarters office and thus relieving the members of the Council.

ELECTIONS

Prof. E. O. Jordan of the University of Chicago was elected to membership on the Committee on Foods. Dr. A. U. Desjardins was elected to succeed himself, and Dr. Yandell Henderson to succeed Dr. H. B. Williams on the Council on

Physical Therapy. Dr. Stephen W. Ranson of Chicago was elected to membership on the editorial board of the *Archives of Neurology and Psychiatry*. Dr. E. H. Cary, F. S. Crockett and C. B. Wright were reappointed to serve as the Committee on Legislative Activities, the first mentioned to act as chairman, and the selection of an auxiliary committee was postponed until a later meeting.

NEW EDITION OF AMERICAN MEDICAL DIRECTORY

The publication of a Thirteenth Edition of the American Medical Directory was authorized and the action of the Board in this respect was reported to the House of Delegates.

DATES OF SECRETARIES' CONFERENCE AND OF FALL MEETING OF BOARD OF TRUSTEES

Since, so far as could be ascertained from the list of meetings published in THE JOURNAL, no meetings of state societies have been scheduled for the week of September 17-23, the Board set the date of its fall meeting as September 21-22 and that of the meeting of Secretaries of State Societies, September 22-23.

RESOLUTION FROM STATE MEDICAL SOCIETY OF WISCONSIN

A resolution from the State Medical Society of Wisconsin, deprecating the declaration of opinions with regard to social, legislative and economic relations of medical practice, except through the approved channels of the American Medical Association, was approved and referred to the House of Delegates.

RESOLUTIONS FROM HOUSE OF DELEGATES

The Board gave careful consideration to resolutions referred to it by the House of Delegates and reported to the latter body the result of its deliberations on these matters.

REORGANIZATION OF THE BOARD OF TRUSTEES

At its last meeting, on Thursday, the Board of Trustees reorganized, and the following officers and committees were appointed: Dr. J. H. J. Upham, chairman; Dr. Rock Sleyster, vice chairman; Dr. Austin A. Hayden, secretary. Executive and Finance Committee: Drs. Rock Sleyster (chairman), D. Chester Brown and Austin A. Hayden. Committee on Scientific Exhibit: Drs. D. Chester Brown, Allen Bunce and Arthur W. Booth.

ADJOURNMENT IN MEMORY AND HONOR OF DR. ALBERT R. MITCHELL

Other matters were given due consideration, and the last meeting of the Board was adjourned in memory and honor of its recently departed chairman, Dr. Albert R. Mitchell.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a. m., Chicago daylight saving time, which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

- July 4. Holiday. No broadcast.
- July 6. Gun Powder.

There is also a fifteen minute talk, sponsored by the Association, on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

- July 8. Rheumatic Fever.

Nuclei of Disease in the Air.—We may esteem ourselves fortunate that the detection of non-radioactive substances is less sensitive than those that have been described. If we could see how many nuclei of dirt, dust, and disease are contained in the air we constantly inhale, we might be terrified and hardly dare to breathe. Nature in her wisdom has arranged matters so that in the course from the ponderable to the imponderable the limits of visibility coincide approximately with the limits of weighability. Let us be thankful that it does not reach down to the individual atoms.—Hahn, Otto: From the Ponderable to the Imponderable, *Science* 77:403 (April 28) 1933.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Appointments to State Board.—Dr. John H. Patterson, Phoenix, was recently elected secretary of the Arizona State Board of Medical Examiners, succeeding Dr. Benjamin M. Berger, Phoenix. Other appointments include Drs. Ira E. Huffman, Tucson, Clarence W. Adams, Globe, and Charles C. Bradbury, D.O., Phoenix, for terms of two years. Dr. William G. Schultz, Tucson, was reappointed a member.

ARKANSAS

Consent for Necropsy.—A verdict in favor of Dr. Harvey S. Thatcher, head of the department of pathology, School of Medicine, University of Arkansas, and his assistant, Dr. Albert F. DeGroat, was rendered by the jury in the case recently brought against them on account of a necropsy done by Dr. DeGroat. The mother of the child on whom the necropsy was performed signed a permit for it. The father was present when she did so, but he did not sign the permit. There were the usual allegations in the suit as to removal of parts of the body, and a necropsy without consent. To guard against similar suits, the rule has been adopted now of requiring both the father and the mother of a deceased child to sign a permit for a necropsy, so that the pathologists may not be made the victims of differences of opinions and desires between the parents, who, under the laws of Arkansas, are joint guardians.

CALIFORNIA

Lectures by Dr. Rosenau.—Dr. Milton J. Rosenau, Charles Wilder professor of preventive medicine and hygiene, Harvard University Medical School, Boston, gave two lectures, June 21-22, before the San Diego Academy of Medicine. His subjects were "Epidemiology and Etiology of Common Colds and Influenza" and "Milk-Borne Diseases and Their Prevention."

Memorial to Physicians.—One hundred and sixty-nine bound volumes and 159 unbound periodicals ranging in date from 1800 to 1898 were recently given to the Barlow Medical Library as a memorial in honor of Drs. Addison P. and Philip K. Strong. Mrs. Philip K. Strong and Mr. Edward A. Strong were the donors. One of the most interesting collections was the *Philadelphia Journal of Medicine*, 1820-1827. The Barlow Medical Library was presented to the Los Angeles County Medical Association last year.

Society News.—Dr. William M. Happ, Los Angeles, addressed the San Diego County Medical Society, June 13, on "Pyuria in Children: A Consideration of Its Causes and Treatment."—Dr. Ludwig A. Emge addressed the San Francisco Pathological Society, May 8, on "Behavior of a Transplantable Benign Mammary Tumor of a White Rat."—Dr. Herbert F. True, Sacramento, was recently installed as president of the Northern California Public Health Association. Leon B. Reynolds, D.Sc., professor of hydraulic and sanitary engineering, Stanford University, was made president-elect, and Dr. Walter H. Brown, Palo Alto, secretary.—Dr. George Dock, Pasadena, discussed "Historical Medicine, with Special Reference to the Discovery of Percussion," before the Hollywood Academy of Medicine and the Los Angeles County Medical Association, June 15.

COLORADO

Society News.—Dr. Vardry A. Hutton, Florence, addressed the Fremont County Medical Society at Florence, May 22, on "Coronary Occlusion."—Dr. Glen E. Cheley, Denver, spoke before the Larimer County Medical Society, May 3, on "Embryology and Surgery of Clefts of the Lip and Palate."—Speakers before the Pueblo County Medical Society in May were Leonard T. Walsh, D.D.S., on "Problems in Orthodontia"; Drs. Ralph S. Johnston, La Junta, "Embolism," and George W. Hawley, Bridgeport, Conn., "New Methods of Treating Fractures."

New Officers of State Board.—Dr. Paul J. Connor, Denver, was recently elected president of the Colorado State Board of Health; Dr. William P. Gasser, Loveland, vice president, and Samuel R. McKelvey, Denver, reelected secretary. Dr. McKelvey will become executive officer of the division

of public health created as a part of the state executive department in a reorganization of the state government by the last legislature. The new division combines all the functions of the state board of health, the meat and slaughter plant inspectors and the state chemist under Dr. McKelvey's supervision, subject to control by the state board of health.

Immunization Program for Denver.—Recommendations framed by the committee on relations with public schools of the Medical Society of the City and County of Denver have been adopted by welfare agencies as the basis of a program of immunization for the city and county. Provision was made for vaccination of all new-born infants occupying free beds at the Denver General and Colorado General hospitals and immunization against both smallpox and diphtheria for all infants admitted to welfare stations. Free immunization of school children in poor districts and of poor children in other districts if certified by the school nurse was recommended. Among other families, parents are to be urged to have their children immunized by the family physician. The committee also recommended that the society sponsor a campaign of education among physicians to prepare them for the work of immunization, including demonstrations of the technique of giving toxoid, the Schick test and smallpox vaccination. In addition, literature on immunization, prepared jointly by the society, the city health department and the school health authorities, will be distributed among parents' organizations, especially if a case of smallpox or diphtheria appears in the schools.

DISTRICT OF COLUMBIA

House Bill to Prevent Blindness.—H. R. 5812, introduced by Representative Watson, Pennsylvania, provides for the prevention of blindness in infants born in the District of Columbia.

Personal.—Wilbur F. Potter, Ph.D., assistant professor of physiology and pharmacology, Medical Department of the University of Georgia, Augusta, has been appointed to a similar position at Georgetown University School of Medicine, Washington. —Dr. A. Ortiz Tirado, orthopedic surgeon and director of the Morelos Hospital, Mexico City, was recently the guest of the Washington Chapter of the Pan American Medical Association and the International Medical Club. Dr. Ortiz Tirado, who also sings, gave a program featuring Mexican songs at the Pan American Union in Washington, June 7.

GEORGIA

Medical School to Be Continued.—A resolution recently adopted by the regents of the University System of Georgia authorizes the continuation of the medical school at Augusta. The closing of the school, effective July 1, had been ordered under a resolution adopted by the regents, April 15. It is understood that the regents had under consideration a plan for consolidating the medical school with the university at Athens.

Society News.—Dr. Joseph Yampolsky presented a paper on treatment of congenital syphilis before the Fulton County Medical Society, Atlanta, May 4. Dr. David Henry Poer discussed thyroid surgery at a meeting, June 15. —The Atlanta Tuberculosis Association observed its twenty-sixth anniversary, April 22. —Dr. John William Shearouse, Savannah, was installed as president of the Georgia Urological Association at a meeting, May 11. Dr. Walter B. Emery, Atlanta, was named president-elect. Dr. Major F. Fowler, Atlanta, was elected secretary, and Savannah was selected for the place of the next meeting in October. Dr. Ernest Corn, Macon, is the retiring president. —At a meeting of the Fifth District Medical Society in Atlanta, speakers included Drs. John D. Martin, Jr., Atlanta, on "Penetrating Wounds of the Abdomen"; Harold M. Bowcock, Atlanta, "Correction of Obesity by Low Calory Diet," and Virgil P. W. Sydenstricker, Augusta, "Dermatomyositis."

ILLINOIS

Society News.—Dr. Edward S. Judd, Rochester, Minn., was the principal speaker before the recent annual meeting of the Lee County Medical Society, on cholecystitis. —Dr. Fred M. F. Meixner, Peoria, addressed the La Salle County Medical Society at Harding, June 7, on "Clinical Aspects of Childhood Tuberculosis."

Chicago

Society News.—Dr. Charles H. Phifer, professor of surgery, University of Illinois College of Medicine, was chosen president-elect of the Chicago Medical Society at its meeting, June 20, and Dr. Thomas P. Foley was elected secretary.

These officers will assume their offices in 1934. Dr. Austin A. Hayden was installed as president of the society at the annual dinner, June 7.

Miller Denied a Rehearing.—The state supreme court refused a rehearing, June 9, to W. H. H. Miller, former director of the state department of education and registration, according to the *Chicago Tribune*, June 10. Miller had been convicted of operating a diploma mill and had served his sentence and paid his fine, but the appeal was an attempt to clear his record (*THE JOURNAL*, May 20, p. 1612).

Personal.—Dr. Philip H. Kreuscher has been appointed medical director of the Industrial Commission of Illinois. It was also announced that the organization of a medical department is planned, to facilitate impartial administration of the workmen's compensation act. —Dr. Loyal Davis was the recipient of an honorary degree of doctor of science from Knox College, Galesburg, Ill., at its annual commencement.

KENTUCKY

Personal.—Dr. Nathaniel A. Mercer has again assumed the directorship of the Adair County health department after a year's study at Harvard University. Dr. Gracie R. Rowntree, who served in Dr. Mercer's absence, has been appointed health officer of Green County, succeeding Dr. Milton W. Williamson. —Citizens of Germantown entertained Dr. Joseph C. Browning at a dinner, March 23, in honor of his fiftieth anniversary in the practice of medicine and his seventy-eighth birthday.

Society News.—Dr. Samuel B. Marks, Lexington, was elected president of the Eye and Ear Section of the Kentucky State Medical Association at its annual meeting in Paducah, May 15. Dr. Lee Wallace Dean, St. Louis, was the guest speaker of the section, which holds its meetings separately from those of the state society. —A symposium on the pancreas was presented before the Jefferson County Medical Society, Louisville, June 5, by Drs. Aura J. Miller, Irvin Abell and Virgil E. Simpson. Dr. Fred W. Rankin, Lexington, addressed the society, June 19, on "The Megacolon, with Special Reference to Sympathectomy Treatment." —Dr. Louis Frank, Louisville, among others, addressed the Licking Valley Medical Society, June 8, at Carlisle, on cancer.

MARYLAND

Portrait Unveiled.—At a memorial meeting, May 27, in the War Memorial Building, Baltimore, a portrait of the late Dr. Charles Hampson Jones, city commissioner of health, was unveiled. Speakers included Mayor Jackson of Baltimore; Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service; Dr. Thomas S. Cullen, representing the Medical and Chirurgical Faculty of Maryland and the state board of health, and Dr. Huntington Williams, commissioner of health. The portrait was unveiled by Dr. Jones's daughter, Mrs. A. L. Rothel. It will be placed in the offices of the city health department. Dr. Jones was associated with the department from 1896 until his death in 1932, the last thirteen years as health commissioner.

MASSACHUSETTS

State Medical Election.—Dr. William H. Robey, Boston, was named president of the Massachusetts Medical Society at its meeting, June 6; Dr. Philemon E. Truesdale, Fall River, vice president, and Dr. Walter L. Burrage, Brookline, secretary, reelected. The next annual session will be held at Worcester, June 11-13, 1934.

Hospital News.—A new unit of the Boston State Hospital, which was to have opened, May 1, will be used as a training center for medical students from Boston University and Tufts College, it is reported. The building will accommodate 150 patients. To project a new method of approach in the treatment of mental disorders, the unit has been constructed with no suggestion of restraint. —Cancer patients will be accepted at the Palmer Memorial Hospital, Boston, in accordance with a recently adopted policy. Although not operated on a purely charitable basis, the institution will no longer be a private hospital.

Dr. Cushing Accepts Professorship at Yale.—Dr. Harvey Cushing, Boston, has been appointed Sterling professor of neurology at Yale University School of Medicine, New Haven, where he will devote himself to literary activities and research to the exclusion of clinical work. Dr. Cushing's laboratories will be in the Sterling Hall of Medicine, in association with the experimental laboratories of preclinical departments of the medical school. He will be the first incumbent of this professorship, which was only recently established, under a \$300,000.

bequest of the late John W. Sterling. It is expected that he will take up his new work this autumn. Dr. Cushing retired from Harvard University Medical School, Sept. 1, 1932, as Moseley professor of surgery, a position he had held since 1912. At this time he also resigned as surgeon-in-chief of Peter Bent Brigham Hospital. Dr. Cushing was associate professor of surgery at Johns Hopkins University School of Medicine, Baltimore, from 1902 to 1912, when he became affiliated with Harvard. Many honorary degrees from medical institutions have been conferred on Dr. Cushing. In 1922 he was awarded the Charles C. Mickle Fellowship of \$1,000 by the University of Toronto Faculty of Medicine. This prize is given to the member of the profession anywhere in the world considered by the faculty to have done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science. In 1923 he was awarded the Distinguished Service Medal. During the World War he was a colonel in the medical corps, and director of U. S. Base Hospital number 5 (Harvard base hospital unit). He received the Lister Medal of the Royal College of Surgeons in 1930. He was president of the American College of Surgeons and the American Neurological Association in 1923, and of the American Surgical Association in 1927. He was the recipient of the Cameron Prize of the University of Edinburgh in 1924. Dr. Cushing's "The Life of Sir William Osler," in 1925, won the Pulitzer Prize for biography.

MICHIGAN

Personal.—Dr. John E. Handy, Caro, was presented with a traveling bag by the Tuscola County Medical Society, May 18, in honor of his having been appointed to the state board of registration in medicine and for his service to the community; he has been a resident of Tuscola County since 1889 and of Caro since 1906. —Dr. Edwin R. Vanderslice succeeded Dr. S. Rowland Hill as health officer of Lansing, May 1; the latter held the position for twelve years.

Memorial to Physician.—A bronze tablet was placed in the Hillsdale Hospital, Hillsdale, May 9, as a memorial to the late Dr. Walter Hume Sawyer, president of the state medical society in 1913, and at one time a member of the state board of registration and education. President Ruthven of the university made the presentation, and Dr. J. Milton Robb, president of the state medical society, represented the medical profession. As a tribute to Dr. Sawyer, the mayor ordered business houses closed for an hour during the afternoon ceremony.

Society News.—Dr. Frederick A. Collier, Ann Arbor, addressed the Oakland County Medical Society, May 18, on "Treatment of Advanced Acute Appendicitis." This was a joint session with the staff of St. Joseph's Mercy Hospital, Pontiac. —At the annual clinic and banquet of the Alumni Association of Detroit College of Medicine and Surgery, June 5, clinics were conducted by Drs. George W. Crile, Cleveland, and Walter C. Alvarez, Rochester, Minn. Dr. Crile was the speaker at the banquet on "Orthogenesis and the Power and Infirmities of Man." —Dr. Adolph E. Voegelin spoke on "Clinical Uses of Oxygen" before the East Side Medical Society, Detroit, April 27. —Dr. Alexander W. Blain was installed as president of the Wayne County Medical Society at its recent annual meeting, and Dr. William J. Cassidy was chosen president-elect. —Dr. Moses Cooperstock, Marquette, addressed the Dickinson-Iron County Medical Society at Iron Mountain, May 12, on "Acute Rheumatic Fever in Children." —Speakers before the Grand Traverse-Leelanau County Medical Society in Traverse City, May 1, included Dr. Paul C. Williams, Ann Arbor, on "Sciatica and Low Back Pain." —At a meeting of the St. Clair County Medical Society in Port Huron, May 16, the speakers included Drs. Clarke M. McColl and John G. Mateer, Detroit, on "Chronic Arthritis: Causes and Treatment" and "Differential Diagnosis of Jaundiced Patients," respectively. —The Kalamazoo Academy of Medicine was addressed, June 20, by John H. Muyskens, professor of speech and general linguistics, University of Michigan, Ann Arbor, on "The Tongues of Men."

MINNESOTA

State Medical Election.—Dr. Francis J. Savage, St. Paul, was elected president of the Minnesota State Medical Association at its recent annual meeting, to serve from January 1. Dr. Edward A. Meyerding, St. Paul, was reelected secretary. Duluth was designated as the place for the next annual meeting in 1934.

Personal.—Dr. Albert Fritsche, New Ulm, has been appointed a member of the state board of medical examiners, succeeding Dr. George B. Weiser. —Dr. William J. Mayo,

Rochester, has left for Scotland, where he will receive the honorary degree of doctor of laws from the University of Aberdeen, the Chicago *Tribune* reported, June 22.

MISSOURI

Tuberculosis Survey.—According to an announcement, May 28, the president of the Missouri Tuberculosis Association was authorized at a conference held in connection with the recent meeting of the Missouri State Medical Association to name a committee to make a survey of tuberculosis control problems in Missouri. The following physicians are on the committee:

Warren L. Allee, Eldon, president of the state medical association.
Elmer T. McLaugh, Jefferson City, state health commissioner.
Stephen A. Newman, superintendent, Missouri State Sanatorium, Mount Vernon.
Hyman I. Spector, senior instructor in internal medicine, St. Louis University School of Medicine.
Jacob J. Singer, associate professor of clinical medicine, Washington University School of Medicine.
Newell R. Ziegler, associate professor of bacteriology and preventive medicine, University of Missouri School of Medicine, Columbia.
John W. Williams, Jr., Springfield, director, Greene County Health Unit.
George H. Hoxie, president, Missouri Tuberculosis Association, Kansas City.

Society News.—Dr. Oscar W. Davidson, Kansas City, was elected president of the Kansas City Urological Society recently. —A joint meeting of the Buchanan County Medical Society and the St. Joseph Clinical Society was addressed, April 19, in St. Joseph, by Drs. John R. Caulk, St. Louis, on "The Cautey Punch Operation for the Removal of Prostatic Obstruction," and Philip C. Jeans, Iowa City, "Certain Practical Aspects of Nutrition in Childhood." —Dr. Quitman U. Newell, St. Louis, spoke on "Diagnosis and Treatment of Carcinoma of the Uterus" before a recent meeting of the Cape Girardeau County Medical Society in Cape Girardeau. —At a meeting of the Clay County Medical Society in Liberty, April 27, Dr. Charles C. Conover, Kansas City, spoke on "Pathology and Therapeutics of the Diseased Heart." —Speakers before the Nodaway County Medical Society in Maryville, April 14, were Drs. Otto Jason Dixon and Morris H. Clark, Kansas City, on "Management of Acute Infections of the Head and Neck" and "Relationship of General Diseases to Diseases of the Eye," respectively.

MONTANA

State Medical Meeting at Anaconda, July 12-13.—The fifty-fifth annual meeting of the Medical Association of Montana will be held at the Montana Hotel in Anaconda, July 12-13, under the presidency of Dr. John R. E. Sievers, Butte. Dr. William E. Long, Anaconda, president, Mount Powell Medical Society, will deliver the address of welcome, and Dr. John A. Evert, Glendive, will respond for the state association. The following will participate in the scientific program:

Dr. Howard C. Naffziger, San Francisco, Encephalography.
Mr. Basil Edwards, Salt Lake City, Utah, Medical Economics.
Dr. Clyde H. Fredrickson, Great Falls, Jaundice as a Complication of Biliary Disease.
Dr. Olin West, Secretary and General Manager, American Medical Association, Chicago, The Future of Medical Practice.
Dr. John de J. Pemberton, Rochester, Minn., Rational Treatment of Toxic Goiter.
Dr. James Tate Mason, Seattle, Problems of Cholecystitis.
Dr. George W. Swift, Seattle, Medical Economics.
Dr. John H. Bridenbaugh, Billings, Radiation Treatment of Carcinoma of the Skin.
Dr. James C. Shields, Butte, Treatment of Compound Fractures.

Dr. Robert C. Coffey, Portland, Ore., will be the banquet speaker on "My European Trip." The Health Association of Montana will meet, July 10-11, and the Montana Academy of Oto-Ophthalmology, July 11. Both will convene in the Montana Hotel.

NEW HAMPSHIRE

Hospital News.—The Christina H. Parker House, a maternity building recently completed at Elliott Hospital, Manchester, at a cost of \$85,000, was opened, April 18. Mrs. Christina H. Parker bequeathed \$50,000 for the building.

Medals to Veteran Members.—Gold medals emblematic of fifty years' membership in the New Hampshire Medical Society were presented at the annual meeting in Manchester, May 15, to Drs. Charles A. Weaver and Charles F. Flanders, Manchester, and Charles B. Drake, West Lebanon. The following, who have completed fifty years of medical practice, were congratulated by the society: Drs. Alpha H. Harriman, Laconia; Nathaniel F. Cheever, Greenfield; William H. Leith, Lancaster; William Hale, Gloucester, Mass.; Charles B. Drake, West Lebanon, and Joseph Theriault, Montreal.

NEW JERSEY

State Medical Election.—Dr. Frederic J. Quigley, Union City, was inducted into office as president of the Medical Society of New Jersey at its annual meeting in June. Dr. Lancelot Ely, Somerville, was chosen vice president and Dr. John B. Morrison, Newark, reelected secretary. The next annual session will be held in Atlantic City in June, 1934.

NEW YORK

Course for Health Officers.—A week's residence course for local health officers was held at Albany Medical College, June 12-17, in cooperation with the state department of health. Among subjects discussed were field epidemiologic work, diagnostic criteria in tuberculosis, typhoid carrier control, milk control, deaths in childbirth and venereal disease. Clinics were presented by Drs. Lemuel Whittington Gorham, on heart disease; Arthur W. Elting, industrial surgery; Rudolph Ruedemann, Jr., syphilis, and Thomas Ordway, undulant fever.

Society News.—A symposium on "Medical Care for the People of Nassau County" was presented before the Medical Society of Nassau County, June 1, by the society's committee on medical economics. Dr. Frederic E. Elliott, Brooklyn, also addressed the meeting on "Financing Sickness."—Dr. Harry K. Tebbutt, Jr., Albany, addressed the Schoharie County Medical Society, Schoharie, May 9, on "Sinus Conditions from the Standpoint of the General Practitioner."—Dr. Samuel G. Gant, New York, was guest speaker before the Dutchess-Putnam County Medical Society, Poughkeepsie, May 17, on "Benign and Malignant Tumors of the Rectosigmoidal Region."—At a meeting of the Broome County Medical Society in Binghamton, June 6, Drs. Eldridge L. Eliason and Thomas Grier Miller, Philadelphia, spoke on "Catastrophes of Peptic Ulcer" and "Commoner Causes of Indigestion with Special Reference to Chronic Gastritis," respectively.

New York City

Courses in Psychoanalysis.—Extension courses in psychoanalysis will be offered during 1933-1934 by the New York Psychoanalytic Institute. They will begin in October. Psychoanalysis in its application to social work, pedagogics, law and medicine will be covered in the courses, in addition to eight popular lectures on the subject.

Personal.—Drs. Foster Kennedy and Joseph Jordan Eller addressed the Academy of Medicine of Mexico City, recently, on "Symptomatology of Expanding Lesions of the Brain" and "Newer Developments in the Treatment of Skin Disease," respectively.—The honorary degree of doctor of science was conferred on Dr. Florence Rena Sabin of the Rockefeller Institute for Medical Research by New York University at its annual commencement, June 6.—A tablet was unveiled, May 16, at Reconstruction Hospital, in memory of the late Dr. William G. Thompson, first president of the hospital.

Resolution on Plastic Surgery.—A resolution directed toward informing the public of the true nature of plastic surgery was adopted by the Society of Plastic and Reconstructive Surgery, May 26. The resolution stated that sensational stories frequently appear in the lay press conveying the impression that plastic surgery is purely for cosmetic purposes. Such stories are designed to appeal to unstable persons who have no genuine deformity, and give the impression that plastic operations can be performed by lay cosmeticians in an environment that does not provide strict asepsis and other safeguards found in a hospital operating room. It was decided to take steps to inform the public that plastic surgery embraces the reconstruction of defects and malformations as well as the repair of gross cosmetic deformities, that plastic surgeons require strict training and that even minor procedures should be performed in first class operating rooms. The society resolved to warn the public of the danger of surgery at the hands of unqualified persons and the unreliability of "sensational, self-aggrandizing publicity."

PENNSYLVANIA

Nine Practitioners Honored.—Nine physicians who have practiced fifty years or more in central Pennsylvania were guests of honor at the annual meeting of the Sixth Council District of the Medical Society of the State of Pennsylvania at Pennsylvania State College, May 11. Certificates were presented to Drs. John L. Brubaker, Juniata; Samuel J. Boyer, Milroy; David Clarence Confer, Duncansville; John P. Getter, Belleville; William L. Lowrie, Tyrone; Vincent I. McKim, Lewistown; Emory H. Morrow, Altoona; James L. Seibert, Bellefonte, and Amos W. Shelley, Port Royal. Drs. Leonard G. Rowntree and John B. Carnett, Philadelphia, presented the

scientific program, speaking on "Advances in Knowledge of the Endocrines" and "Neuralgic Pain in All Parts of the Body," respectively.

Society News.—Dr. William K. Kalbfleisch, Wheeling, W. Va., among others, addressed the Washington County Medical Society, Washington, June 14, on "Roentgenological Diagnosis of Intestinal Obstruction."—Dr. William H. Crawford, Philadelphia, addressed the Delaware County Medical Society, June 15, at the Springhaven Country Club, on "Infant Feeding and Summer Care."—Dr. Karl Kornblum, Philadelphia, addressed the Northampton County Medical Society, May 19, on "The Value of the Roentgen Examination in Modern Medical Practice."—Dr. Dean Lewis, Baltimore, President, American Medical Association, addressed the York County Medical Society, May 20, on differential diagnosis of bone lesions.—Dr. Henry T. Price, Pittsburgh, addressed Cambria County Medical Society, Johnstown, June 8, on "Malnutrition and Diet in Children," and Dr. John Paul McCloskey presented a review of research on the nose and throat.

Philadelphia

University News.—Dr. Haven Emerson, New York, addressed the graduating class of the Woman's Medical College of Pennsylvania at the eighty-first annual commencement, June 7, on distribution of medical care. At the annual alumnae banquet, among other speakers, Dr. Carroll L. Birch, Chicago, spoke on hcmophilia and Dr. Robert T. Frank, New York, on the present status of the sex hormone. Dr. Julia Faith Skinner Fetterman was elected president of the Alumnae Association.

Hospital News.—The cornerstone of the Fridenberg Memorial Surgical Building of the Jewish Hospital was laid, June 7. The building will be a memorial to Samuel M. and Esther Fridenberg and their three sons, under the provisions of the will of Monc Samuel Fridenberg.—A new building for the Skin and Cancer Hospital of Philadelphia will open in September with a staff of forty physicians under the direction of Dr. Albert Strickler. The four story building will give twenty-two beds to the hospital, which has hitherto been only a dispensary. It is the gift of an anonymous member of the board of trustees. Special emphasis is planned on research in dermatologic and neoplastic fields, for which pathologic, tissue culture and chemical laboratories are now available.

Student Prizes.—Three prizes for research in medicine were awarded to students in the University of Pennsylvania School of Medicine at a recent meeting of the undergraduate medical association. Franklin M. Kern, Philadelphia, and Leon S. Smcdo, Elkins Park, won the Mary Ellis Bell prize of \$50 and a medallion for a study of saccharoids. Josiah K. Wallis, Malvern, James V. D. Quereau, Reading, and Laurence M. Wiig, Fort Landerdale, Fla., received the John G. Clarke prize of a gold key and \$50 for research on the effect of divinyl ether on the livers of dogs and monkeys. Nathaniel Gildersleeve, Lansdowne; Ross E. Hobler, New York, and William V. Rucker, Bedford, won the Grayhe Simpson Priestly prize of \$25 for a study of the cytology of aseptic peritoneal exudate in the mouse.

Medicine and Dentistry to Be Coordinated.—A half century of progress in dentistry at the University of Pennsylvania was recently celebrated at a special convocation. Addresses were delivered by Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service, on "The Relation of Dentistry to Public Health" and Herbert S. Jennings, LL.D., Baltimore, on "The Biologist's Outlook on the World." A new plan for coordination of the medical and dental schools in the university was announced by President Thomas S. Gates at a dinner following the convocation. Under the arrangement just completed, the professor of medicine in the medical school will assume a chair of the same name in the dental school. Training for dental students in the future will include medical clinics and laboratory work and a hospital internship, he said.

Personal.—Dr. Spencer Leon Israel, chief resident physician at Mount Sinai Hospital, has been awarded the Henry B. Shmookler Memorial Fellowship for graduate medical study by the board of trustees of the hospital. Dr. Israel will study gynecology in Vienna and in Lund, Sweden.—Dr. and Mrs. William E. Hughes celebrated their fiftieth wedding anniversary, May 26.—Dr. Wilmer Krusen, president of the Philadelphia College of Pharmacy and Science, received the honorary degree of doctor of science at the commencement exercises of Franklin and Marshall College, Lancaster, June 7.—Dr. Chevalier Jackson professor of bronchoscopy and esophagography, Temple University School of Medicine, has accepted an invitation to teach three months each year at Louisiana State Uni-

versity School of Medicine, New Orleans.—Dr. Hermann Nunberg, Vienna, Austria, has returned to the Institute of the Pennsylvania Hospital to continue analytic work, according to an announcement from the institute.—Dr. Louis H. Clerf was recently elected president of the Philadelphia Laryngological Society.

RHODE ISLAND

State Medical Election.—Dr. Charles S. Christie, West Warwick, was installed as president of the Rhode Island Medical Society at its annual meeting, May 18. Dr. Albert H. Miller, Providence, was named president-elect, and Dr. James W. Leech, Providence, was reelected secretary.

SOUTH CAROLINA

Society News.—Dr. Edward P. White, Gaffney, health officer of Cherokee County, was elected president of the South Carolina Public Health Association at the recent annual meeting in Spartanburg.—Dr. Watson S. Rankin, director of the hospital and dependent children's section of the Duke Endowment since June 1, 1925, was the speaker at the commencement exercises of the Medical College of the State of South Carolina.

Personal.—Dr. George R. O'Daniel, St. George, has resigned as health officer of Dorchester County, effective May 19. Dr. O'Daniel plans to reenter private practice in Hartsville.—Dr. John C. Caldwell, Chester, was appointed a member of the state board of medical examiners, May 9, succeeding Dr. Robert E. Abell, Chester, resigned. Drs. Joseph T. Taylor, Adams Run, and Frank Lander, Williamston, were reappointed members.

WASHINGTON

Hospital Renamed.—The Martha Washington Hospital, Seattle, has been renamed Maynard Hospital in honor of Seattle's first physician, Dr. David S. Maynard, according to *Northwest Medicine*. In 1850, Dr. Maynard crossed the plains and settled in Olympia, and located at Alki Point in 1852, before Seattle was founded. Dr. Maynard, who died in 1873, established the first hospital in Seattle.

Health at Tacoma.—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended June 17, indicate that the highest mortality rate (18.1) appears for Tacoma and that the rate for the group of cities as a whole is 10.6. The mortality rate for Tacoma for the corresponding week of last year was 9.6 and for the group of cities, 10.1. The annual rate for eighty-five cities for the twenty-four weeks of 1933 was 11.6, as against a rate of 12.1 for the corresponding period of the previous year.

WISCONSIN

State Medical Election.—Dr. Thomas J. O'Leary, Superior, was named president-elect of the State Medical Society of Wisconsin at the annual meeting in Milwaukee, June 13. Dr. Stanley J. Seeger, Milwaukee, was installed as president. The society dispensed with its scientific program because of the annual session of the American Medical Association in Milwaukee, June 12-16. It was voted to hold the 1934 session in Green Bay.

GENERAL

Changes in Status of Licensure.—The Commission on Licensure of the Healing Arts Practice Act of the District of Columbia reported the following:

Dr. Clarence A. Wright, license revoked, May 26. He has been convicted and sentenced to jail for performing illegal operations.

The Board of Medical Examiners of the State of Oregon reports the following:

Dr. Charles H. Rogers, Portland, license restored, February 1. The license was revoked, April 3, 1930.

Collection of Documents of Ophthalmologists.—The American Ophthalmological Society has formed a committee to collect autographs, letters and other documents, portraits and objects of interest relating to the early ophthalmologists of the country, to be placed in the Army Medical Library at Washington, D. C. Members of the committee are Drs. Harry Friedenwald, Baltimore; Arnold Knapp, New York, and Burton Chance, Philadelphia. They ask the cooperation of all ophthalmologists in the undertaking. Inquiries will be answered by Dr. Friedenwald, 1212 Eutaw Place, Baltimore.

Reduction in Veterans' Benefits Modified.—Legislation modifying the stringent reductions in veterans' benefits recently ordered under the Economy Act was enacted in the closing sessions of Congress. Reductions as finally agreed on will save about \$320,000,000 annually, \$100,000,000 less than the

savings originally planned. The President is authorized to appoint special boards to review claims in which presumptive service connection has been granted, provided the veteran entered service prior to Nov. 11, 1918, and provided the disability is not the result of his own misconduct. Neuropsychiatric diseases if developed within a year and tuberculosis if developed within two years are presumed to be of service origin. Under the original regulations issued in March, all non-service-connected cases except persons totally and permanently disabled were removed from the rolls. The final compromise also guaranteed that compensation in service-connected cases will not be reduced more than 25 per cent.

Meetings of Psychiatrists.—Dr. George H. Kirby, New York, was elected president of the American Psychiatric Association at the annual meeting in Boston, May 29-June 2. Dr. Charles F. Williams, Columbia, S. C., was made vice president and Dr. William C. Sandy, Harrisburg, Pa., secretary. Among speakers at the meeting were:

Dr. Charles J. C. Earl, Caterham Mental Hospital, Surrey, England, who displayed drawings made by mental defectives.

Dr. Abraham A. Brill, New York, Homerotism and Paranoia.

Drs. Lawrence O. Morgan, Cincinnati, and Hugh S. Gregory, Binghamton, N. Y., Changes in the Tuber Cinereum Region in the Psychoses.

Dr. Leland E. Hinsie, New York, Determinants of Adequate Psychotherapy in a Public Mental Hospital.

Dr. Meyer Solomon, Chicago, The Struggle for Equilibrium.

Drs. Bernard T. McWhie and George C. Brink, Toronto, A Tuberculosis Survey in Mental Hospitals.

Dr. Earl D. Bond, Philadelphia, and Willem Van de Wall, D.M.S., New York, Uses of Music in a Case of Psychoneurosis.

Dr. Stanley Cobb, Boston, Cerebral Anemia.

Drs. Hiram Houston Merritt, Jr., and Merrill Moore, Boston, The Argyll Robertson Pupil.

Dr. Abraham Myerson, Boston, Social Psychiatric Aspects of the Minor Delinquent.

Society News.—Dr. W. Gordon M. Byers, Montreal, was installed as president of the American Ophthalmological Society at its annual meeting, May 29, and Dr. Walter B. Lancaster, Boston, was named president-elect. Dr. John Milton Griscom, Philadelphia, was reelected secretary. The next annual session will be held in Lucerne-in-Quebec, Canada, July 9-11, 1934.

—Dr. John R. Page, New York, was installed as president of the American Otological Society at its recent annual meeting; Dr. Samuel J. Crowe, Baltimore, was named president-elect, and Dr. Thomas J. Harris, New York, reelected secretary.

—Officers of the American Laryngological Association are Drs. George M. Coates, Philadelphia, and William V. Mullin, Cleveland, president and secretary, respectively. —At the annual meeting of the American Climatological and Clinical Association, Dr. Charles D. Parfitt, Gravenhurst, Ont., Canada, was made president, and Dr. Francis M. Rackemann, Boston, secretary. The next annual session will be held in Toronto in May, 1934.—Dr. Charles A. Fife, Philadelphia, was named president of the American Pediatric Society at its annual meeting, May 10, and Dr. Hugh McCulloch, St. Louis, reelected secretary. The next annual session will be held at Grove Park Inn, Asheville, N. C., in May, 1934.—Officers of the American Gynecological Society, elected at the annual meeting, May 9, are Drs. Frank W. Lynch, San Francisco, and Otto H. Schwarz, St. Louis, president and secretary, respectively.

—New officers of the American Gastro-Enterological Association, elected May 8, are Dr. John Bryant, Boston, president; Dr. B. B. Vincent Lyon, Philadelphia, first vice president, and Dr. Russell S. Boles, Philadelphia, secretary.—Dr. Israel Strauss, New York, was made president of the American Neurological Association at its annual meeting, May 10, and Dr. Henry Alsop Riley, New York, reelected secretary.—Dr. Harvey Cushing, Boston, and Dr. John T. King, Jr., Baltimore, will continue as president and secretary, respectively, of the Congress of Physicians and Surgeons of North America. The next congress will be held in 1938.—Dr. Daniel F. Jones, Boston, was elected president of the American Surgical Association at its annual meeting, May 8-10; Drs. LeGrand Guerry, Columbia, S. C., and John L. Yates, Milwaukee, vice presidents, and Dr. Vernon C. David, Chicago, secretary. The next annual session will be held at Toronto in May, 1934.—At the annual meeting of the American Laryngological, Rhinological and Otological Society, June 8, Dr. James W. Jervey, Greenville, S. C., was elected president, and Dr. Robert L. Loughran, New York, reelected secretary.—The twenty-second annual meeting of the Pacific Coast Oto-Ophthalmological Society was held at the Fairmont Hotel in San Francisco, June 28-30, with Dr. George L. Tobey, Jr., Boston, as the guest speaker.—Dr. Edward S. Godfrey, Jr., of the New York State Department of Health, Albany, was elected president of the American Epidemiological Society at the recent annual meeting in Washington, D. C.—The next annual convention of the American Red Cross will be held in Washington, D. C., April 9-12, 1934.

HAWAII

Territorial Election.—Dr. Arthur C. Rothrock, Paia, Maui, T. H., was elected president of the Hawaii Territorial Medical Association at its annual meeting in Honolulu, May 1. Dr. Lyle G. Phillips, Honolulu, was reelected secretary. The next annual session will be held on the island of Kauai. Guest speakers were Drs. William S. Middleton, Madison, Wis., on nephritis, and Barney Brooks, Nashville, Tenn., on arterio-venous aneurysm. In addition to a clinic on leprosy by Dr. Newton E. Wayson, the program also included papers by the following Honolulu speakers:

Dr. Nils P. Larsen, G. P. Pritchard, D.D.S., and Martha Jones, Ph.D., *Medicodental Research in Hawaii*.
Dr. Francis H. A. Gaudin, *Aspects of Artificial Feeding of Infants*.
Dr. Joseph W. Lam, *Vasectomy*.
Dr. Forrest J. Pinkerton, *Leprosy of the Eye, Ear, Nose and Throat*.

CANADA

Personal.—Dr. John A. Amyot, for fourteen years deputy minister of national health and, more recently, of pensions and national health, has retired because of ill health. From 1900 to 1919 he was associated with the provincial department of health of Ontario and also with the public health teaching staff at the University of Toronto.

Academy Honors Dr. Bruce.—The Toronto Academy of Medicine gave a dinner, March 27, at the Royal York Hotel in honor of Dr. Herbert A. Bruce, who was recently appointed lieutenant-governor of the province of Ontario. Dr. Reginald S. Pentecost and Dr. Harry B. Anderson paid tribute to Dr. Bruce in addresses, to which he responded. A portrait of the lieutenant-governor by Joshua Smith was presented to the academy by Mrs. Bruce, who officiated at the unvailing.

Society News.—The Canadian Pharmaceutical Association will hold its annual session, August 21-25, in Montreal. — Dr. Arthur J. Bedell, Albany, N. Y., addressed the Toronto Academy of Medicine, March 7, on "Ophthalmoscopic Interpretation of Blood Vessel Changes." Dr. Allen O. Whipple, New York, spoke, February 7, on "The Type of Carcinoma in Its Relation to the Operability and Late Results in Carcinoma of the Stomach." — The Canadian Public Health Association held its annual meeting in St. John, N. B., June 19-21, in conjunction with the meeting of the Canadian Medical Association. Among other speakers, Sir Humphry Rolleston, London, England, and Col. Lyle Cummins, Cardiff, Wales, was to participate in a program devoted to tuberculosis.

FOREIGN

Congress Postponed.—The ninth annual congress of the Far Eastern Association of Tropical Medicine, which was to have been held in Nanking, China, October 2-8, has been postponed. Announcement of the place and date of meeting will be made later.

Society News.—The first French Congress of Therapeutics will be held in Paris, October 23-25, under the presidency of Dr. Loeper. Papers will be presented on the following subjects: parenteral treatment of gastric ulcer; treatment of colibacillosis; the suprarenals; short waves in therapeutics, and treatment of radiodermatitis. For information apply to Dr. G. Doin, 8 Place de l'Odéon, Paris.

Orthopedic Congress.—The second International Congress for Orthopedic Surgery will meet in London, July 19-22, under the presidency of Professor Nové-Josserand, Lyons, France. Subjects to be discussed the first two days are the mechanism of articular movements and the treatment of tuberculous hips. The third day will be devoted to special papers, some of which will be given by Drs. Willis C. Campbell, Memphis, Tenn.; Arthur Steindler, Iowa City; Walter G. Stern, Cleveland, and Dr. Lorenz Boehler. There will be operative clinics in several London hospitals. Meetings will be at the headquarters of the Royal Society of Medicine, 1 Wimpole Street, where members of the congress are asked to register as soon as they arrive in London. Dr. Fred H. Albee, New York, is chairman of the American committee.

Deaths in Other Countries

Sir Walter Morley Fletcher, Kensington, London, secretary of the Medical Research Council, died June 7.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 3, 1933.

The London Voluntary Hospitals

King Edward's Hospital Fund for London, which was founded in 1897 to collect money for the support of the voluntary hospitals, has distributed \$37,000,000 in the period which has elapsed. The report for 1932 is satisfactory under the circumstances. The financial depression compelled some of the subscribers to the voluntary hospitals to reduce or discontinue their contributions. A special effort was therefore made to obtain additional subscriptions and to effect economies so as to avoid the closing of beds. So successful has this been that a small aggregate balance on the right side will again be shown. There was a slight decrease in income, but this has been more than offset by the reduction of expenditures. The total receipts of the king's fund for the year were \$1,630,000, and \$1,500,000 was distributed to the hospitals. The number of pay beds provided by the voluntary hospitals of London at the end of 1932 was 1,667 at 105 hospitals against 577 at 104 hospitals in 1931. The charges for these beds range from \$10 to \$50 a week, exclusive of medical and surgical fees. During June last the scheme of the British Provident Association which enables members of the professional and middle classes to make provision toward the cost of treatment in a pay bed was launched. A committee of the fund inquired into outpatient methods as affecting the suitability of patients and the time of waiting, about which complaints had been made. The conclusion was that part of the waiting was unavoidable, because of the large populations dealt with, but that part was due to the treatment of an excessive number of minor cases, which could be dealt with by other agencies. The committee recommended that the present movement toward the more consultative use of outpatient departments, except for emergencies, should be encouraged, except that a patient desiring to attend a hospital and unable to pay a consultation fee should have access without a physician's letter. Considerable results had followed from the recommendation that the hour of waking patients in the morning should not be earlier than 6 o'clock. The number of hospitals in which this practice had been adopted had increased during the year from forty-seven to sixty-nine, while fifteen others made changes in the desired direction.

The Transmutation of the Elements

Before a distinguished audience, including Professor Einstein and Dr. H. N. Russell, professor of astronomy at Princeton University, Lord Rutherford delivered the annual Boyle lecture of the Junior Scientific Club, Oxford. He referred to the fascination exercised over men's minds, since the dawn of science, by the possibility of the transmutation of the elements. Progress in such transmutation had been made by producing and speeding up intense streams of protons and other particles. The most obvious way to obtain very fast protons was to allow the stream to pass through a highly evacuated space to which a high difference of potential of the order of a million volts was applied. The first successful application of the high voltage method of generating fast particles for producing atomic transmutation was made by Cockcroft and Walton last year in the Cavendish laboratory. To carry out experiments at low voltages, Lord Rutherford and Dr. Oliphant designed an apparatus to obtain much narrower and stronger proton beams of the order of 100 micro-amperes. They found that the transmutation of lithium could easily be observed when the proton had an energy of only 30,000 volts. "In a sense we are opening up today a new branch of knowledge—nuclear chemistry—

where we deal with the combination and dissociation, not of atoms as a whole, but of the ultimate units which make up the minute world of the nucleus."

Bill to Insure Payment for Road Accidents

Lord Moynihan has introduced a bill into the house of lords which provides that a physician or hospital rendering emergency treatment for bodily injury arising out of the use of an automobile on a road shall be entitled to recover reasonable remuneration not exceeding \$15 from the owner of the automobile, in the same manner as if the treatment were rendered at his request. In addition, the physician will be entitled to recover 12 cents for every mile beyond 2 miles traveled by him in complying with the call, notwithstanding that the injured persons may have died before receiving treatment.

The Assistance of Refugees from Germany

The formation of the Academic Assistance Council to assist scholars and men of science who have lost their positions in consequence of the German persecution has been reported in a previous letter. The president of the council is Lord Rutherford and the most eminent scientists, including those of the medical profession, are supporting the movement. At the first meeting of the council, held at the headquarters of the Royal Society, it was reported that distinguished scholars continue to be discharged or have their lives rendered intolerable in German universities. The council proposes to provide for them on a temporary basis by grants which will not interfere with British workers in similar fields. The council is in contact with similar bodies in France, Switzerland, the United States, Holland and Belgium, so that any overlapping will be avoided. There is hope of accommodating a large proportion of the dispossessed academic class in existing institutions, the reputation and activity of which will be increased. It is impossible to estimate the number of teachers of high academic rank who have been discharged or forced to resign from German universities, but the number is in the neighborhood of 400. Among them are several professors of theology. A number of distinguished physicists have left the University of Berlin, and the great mathematical school at Göttingen has been deprived of some of its most eminent exponents. Philosophy and medical research have suffered heavily everywhere.

Another organization that is offering help is the Cambridge branch of the All People's Association, which has taken steps to welcome visitors from foreign countries who are likely to come to Cambridge. The association has received offers of hospitality for such cases.

Congress of Urologists

The fifth congress of the International Society of Urologists will be held in London in July under the presidency of Sir John Thomson-Walker. He will hold a reception on the 10th, and on the following morning Prince Arthur of Connaught will formally open the congress at the house of the Royal Society of Medicine. The three principal subjects chosen for discussion are tumor of the renal pelvis and ureter, by Prof. Salvador Pascual, Prof. F. Van den Branden and Mr. J. Swift Joly; pyelography by the descending route, by Prof. A. von Lichtenberg, Prof. C. Ravasini and Mr. R. Ogier Ward, and surgery of the neck of the bladder, by Prof. G. Marion, Prof. J. Weijtland and Mr. Kenneth Walker. There will be receptions by the government, the lord mayor of London and the Royal College of Surgeons.

Children and Accidents

At the National Safety Congress, now being held in London, G. H. Gater, of the London County Council, read a paper in which he said that in Great Britain approximately 4,000 children lost their lives each year in accidents, about half of which occurred in the home and the other half in traffic. The greatest

incidence was between the ages of 5 and 9 years. The solution of the problem lay in the development of a keen sense of self-preservation which unconsciously shaped conduct in traffic, and that is one of the tasks of those charged with the education of the child.

Fee Splitting Denounced

Sir Norman Walker, president of the General Medical Council, stated at the last meeting that he was informed that the practice of fee splitting, which he had heard was regrettably prevalent in other countries, was raising its head in this country. He wished that he could think that his information was incorrect. The essence of the offense was that, unknown to the patient, part of the consultant's fee was paid to the physician who advised the consultation. The commission was thus secret and the receipt of such a commission was recognized in this country as against the public interest and was forbidden by law. A conviction under the act for punishment of corrupt transactions would inevitably bring the offender under the jurisdiction of the council.

Undue Fear of Tuberculosis

The Comité national de défense contre la tuberculose has published an article by Prof. Léon Bernard, designed to put the public on its guard against undue fear of tuberculosis. By the number of placards urging the avoidance of contagion by refraining from spitting in public places, a veritable psychosis has been created in the minds of persons who were predisposed. The fear of tuberculous contagion haunts them. They take ridiculous precautions. As soon as they cough they consult a physician, demanding that they be examined and radiographed, or they use self-medication recommended by advertisements in the daily press. They go from one physician to another, until they finally encounter a charlatan who exploits their credulity. Another class are those who have a tuberculous patient in the family. They go to extremes in protecting the patient, demoralizing him, whereas he may not be contagious at all. These overworried persons communicate their phobia to those about them. In workrooms they demand the dismissal of an employee who coughs. In the large hotels along the Mediterranean border, it frequently happens that the house steward, at the instance of certain clients, requests any one who coughs too often to procure a statement from his physician that he is not affected with tuberculosis, on pain of expulsion. The worst part of the situation is that persons who are actually tuberculous, feeling themselves the objects of surveillance, seek to conceal their condition for fear of losing their employment; neglect to visit a dispensary for fear of being observed there, and fail to take proper care of themselves. Mr. Léon Bernard called attention to the real conditions under which tuberculosis becomes contagious, emphasizing that contagion is rare between adults, except under peculiar circumstances. On the contrary, he stressed the need of establishing immunity in childhood by early inoculation with BCG vaccine.

The Pathogenesis of Peptic Ulcer

In an address before the Société des chirurgiens in Lyons, Professor Leriche and R. Fontaine reported the results of a long series of experiments on the genesis of peptic ulcer. They employed the Mauss method, which consists in the withdrawal of digestive fluids (biliary and pancreatic). They succeeded in all cases in producing typical ulcers. When later the normal insertions of the tracts are restored, the ulcers heal. Leriche does not accept the explanation ordinarily given, namely, the suppression of the duodenal reflux toward the stomach. He regards such reflux as a doubtful feature of normal digestion. Leriche thinks that the protective rôle of the mucosa belongs rather to the mucus. But this has a tendency to dissolve and

to disappear in an alkaline medium. That is perhaps the reason why ulcers develop more commonly on an alkaline mucosa. This conception is partly confirmed by the fact that the ulcer can be prevented, even after withdrawal of the digestive fluids, if the patient is allowed to ingest a daily dose of mucin.

Color of the Eyes and Puberty

A communication has been presented to the Academy of Medicine by Mr. Paul Godin of Nice on the "Evolution of the color of the eyes under the influence of puberty." The color of the eyes is due to the pigmentation of the iris, but in 50 per cent of adolescents the pigmentation changes its color several times during the onset of puberty. The iris is formed by two concentric circles diversely colored. The colors are distributed in the form of striae, specks, stippling and rays, on a colored background. They appear, disappear and are transformed from one form into another, until a more or less complete change in the primary coloration of one of the zones, and often of both, is brought about. This evolution ends generally in a "lightening" of the original color in both girls and boys, but without following any fixed rules. Light eyes and delayed puberty are often accompanied by numerous changes. A judicial expert finds herein the key of the problem that develops when a delinquent aged 17 years no longer has the blue eyes recorded on his anthropometric chart made out at age 15. A complete "oculochromatic scale" was prepared on the basis of 100 observations made during the course of this research.

The Medical Convention of Bordeaux

The medical convention (*journées médicales*) of Bordeaux was devoted to the subject of cancer. At the opening session, under the chairmanship of Professor Bounhiol, communications on the etiology of cancer were presented by Malvesin Fabre and Lague, Delangière, Bounhiol, Manques of Toulouse, Pfeiffer of Dijon, and Prof. Nello Mori of Naples. The second day's session was presided over by Professor Mori.

Purification of the Air

Gaston Menier, chocolate manufacturer and senator of the department of Seine-et-Marne, has devised a simple procedure for purifying the air of his factories. Mr. d'Arsonval recently described the method before the Academy of Sciences. Menier conceived the idea of constructing an apparatus consisting of an endless canvas sheet held vertically between two electrically driven rollers. The lower part of the canvas passes through a trough containing a solution, which keeps the canvas moist. An electric fan drives the air against the canvas. The dust and germs become attached to the canvas and are collected in the trough below. Experiments have shown that the purification of the air in this way is practically complete in thirty minutes. When used in a freight car filled with particles in suspension and with toxic gases, the apparatus effected simultaneously an absorption of the carbon monoxide and a bacterial purification of the air. The procedure enables one to maintain also a certain degree of humidity in a heated room.

Creation of an Institute of Industrial Medicine

A decree of the minister of public health has established a course in industrial hygiene to be given at the *Faculté de médecine* de Paris. The plan is to attach directly to the *Faculté de médecine* centers of study now located in the biologic center at Auteuil and at the *Institut d'hygiène industrielle*. The new courses will provide instruction for medical students desiring to prepare themselves as health officers or inspectors of physiologic conditions of work in factories. The course will consist of three parts: (1) industrial hygiene, (2) occupational medicine and (3) chemical toxicology of industry, dealing with the rendering of expert chemical opinions pertaining to industrial poisoning. Three special courses will

be created corresponding to the three subdivisions, together with a graduate course comprising a series of lectures on industrial hygiene. The lectures will be given by professors and associate professors of the *Faculté de médecine*, and likewise by qualified persons not belonging to the *Faculté*. The lectures will be supplemented by practical work, including visits to factories, examinations of workmen, study of sanitation projects, the detection of harmful factors in an industrial environment, and the application of the teachings of industrial toxicology. The institute will grant a diploma in industrial hygiene and occupational medicine, which will furnish evidence of the ability of candidates to perform the duties of an industrial physician.

Service Medals Awarded to Physicians

The municipal council of Paris conceived the idea of holding special ceremonies at which its president, Mr. de Fontenay, awarded medals to the chief physicians of the hospitals of the Assistance publique who had completed twenty-five years of such service. This ceremony emphasized the disinterested nature of the duties of the chief physician of a hospital service. Such posts are much sought after, and the recruiting of the incumbents by means of severe tests assures the selection of élite candidates unaffected by political influence. The position bestows professional prestige and the best chances of achieving success. The salary schedules are low and are regarded more as reimbursement for traveling expenses. The number of physicians, surgeons and specialists who had completed twenty-five years of service was 132 and represented the medical élite of Paris. Mr. de Fontenay, in connection with the awarding of the medals specially struck for the occasion, delivered an address in which he expressed the gratitude of the people of Paris for their long and devoted service.

BERLIN

(From Our Regular Correspondent)

May 28, 1933.

Changes in Regulations Controlling Narcotics

In a decree of the federal minister of the interior, May 20, the regulations governing the medical prescribing of opiates and cocaine were modified to meet the demands of the medical profession with respect especially to the prescribing of cocaine. From June 1, 1933, on, cocaine not to exceed 2 per cent may be prescribed for use on the eyes as an ointment in place of a solution, which heretofore has alone been permitted, provided the presuppositions with respect to indications noted in *THE JOURNAL*, Feb. 28, 1931, page 706, obtain; that is to say, if the use of cocaine is unavoidable and the substitutes are inadequate. Prescriptions calling for the pure substance are still prohibited. With respect to cocaine ointment, it is stipulated, as for the solution, that the maximum of 0.1 Gm. of cocaine salts must not be exceeded. In addition to the amount prescribed directly "for a patient," the decree provides also that a certain amount may be secured for the needs of general practice. The maximum amount that may be secured per day remains unchanged (1 Gm.). Whereas the former decree permitted no dilution stronger than 10 per cent, now a 20 per cent concentration may be prescribed, or an ointment may be prescribed with a maximum concentration of 2 per cent in quantities of 50 Gm., containing a maximum of 1 Gm. of cocaine salts. The physician's entries in the "cocaine book" must still be made punctiliously, although certain welcome changes have been made. The regulations concerning the prescribing of opiates and the entries in the "morphine book" remain unchanged, as no serious objections to them were raised by the profession.

Now that two years has elapsed since the regulations greatly restricted the physician in prescribing opiates and cocaine, the effects can be measured to some extent. The examination of

prescriptions for remedies containing narcotics has given a favorable impression (all such prescriptions must be retained and preserved by the pharmacist for inspection) and there has been a marked decline in the consumption of narcotics, which is due partly to the smaller number of addicts (THE JOURNAL, Oct. 17, 1931, p. 1161). That the decline has not come at the expense of patients who actually need narcotics may be seen from the fact that, during the deliberations concerning the new decree, the representatives of the medical profession unanimously opposed any fundamental changes in the decree. The more moderate regulations of the new decree are due to the demands of the ophthalmologists and the ear, nose and throat specialists.

In the official *Reichsgesundheitsblatt* is found the statement "Owing to the strict compliance on the part of the medical profession, the consumption of narcotic drugs in 1932, as compared with 1930, declined 35 per cent in respect to morphine, 49 per cent for opium, 89.5 per cent for heroin and 80.5 per cent for cocaine. The regulations controlling the prescribing of cocaine preclude all possibility of catering to the demands of drug addicts." (THE JOURNAL, June 18, 1932, pp. 2179, 2180, 2182.)

Employment for the War Injured

A report of the federal minister of labor on the employment in federal bureaus of persons severely injured in the war shows that 4.07 per cent of the positions in federal bureaus were held by such persons. The highest percentage (10.77) is found in the federal ministry of labor; the federal postal ministry has 5.28 per cent; the federal ministry of finance, 4.97 per cent, and the federal railway system, 3.42 per cent. Other bureaus have smaller percentages.

Sex Education in the Home

The opinions of official circles on "Sex Instruction in Schools" have been announced, and there is general agreement that sex instruction of youth devolves on the home and not the school. Rust, the Prussian minister of public instruction, who has expressed his views in a special announcement, says that the sex instruction of youth has its foundation in the demands of religious and moral education and in the interest of health of body and mind of future generations. The question cannot be solved by the awakening of intellectual insight or by instruction in pure utilitarian ethics, incorporated in the general curriculum. Sex instruction cannot, in the nature of the case, be imparted to a large class. Nevertheless, supervisory boards should not be denied the privilege of demonstrating the possibilities of sex instruction. The minister declared, as a matter of principle, that all sex instruction must take development as its fundamental basis and must call into action all educational forces available in the home, the school and the community, and the religious solidarity of all persons concerned. It must be based also on the principle of awakening in the youth all ethically significant forces: will power, conscience, natural modesty and religious association. Sex instruction should deal primarily with (1) relation between morality and the sex impulse, as based on the personal, social and religious responsibility of the individual, (2) necessary biologic instruction on the general subject of propagation, and (3) the menace to health of an uncontrolled sex impulse. In principle, enlightenment in matters of sex devolves on the home. The school, however, has the task of supplying instruction by special meetings for parents, talks to mothers and individual discussion on the duties of this phase of education. Persons selected from the medical profession may be well utilized for such general instruction. An excellent method has already been established in some places. If the home fails, an understanding may be reached with the parents, and a male teacher may give private instruction to the boys and a woman teacher may do the same for the girls; it may be desirable in some cases to have a previous understanding with the family pastor and the family

physician or the school physician. The minister emphasized the need of considering each individual case separately, care being taken to avoid any appearance of compulsion. The success of these educational measures will determine to a great extent the moral character of youth and thus the moral qualities of the people as a whole.

MADRID

(From Our Regular Correspondent)

May 10, 1933.

Medical Problems in Spain

Dr. L. N. de Castro recently delivered a lecture on the unfavorable conditions of physicians in Madrid. In 1896 the number of students registered at the faculty of law was three times the number registered in the faculty of medicine. During the last seven years (1924 to 1932) the Faculty of Medicine of Madrid has had a greater number of students than any other school. At present there is a surplus of physicians and it constitutes a danger both for the physician and for the patient. A still greater danger is the insurance societies, which are supposed to give their members medical care and drugs during their illness and burial when they die. The societies for mutual insurance are as dangerous as the insurance societies. Generally speaking, both the physician and the patient cannot derive any benefit from these societies, which only exploit them. The members of the societies are made fabulous promises which never come true. They pay monthly fees, and when they are in need of special care they are not given satisfactory attention, and so they prefer to go to their own physicians. Dr. Castro believes that the only advantage of the insurance societies is to give their members a decent funeral. On account of the general economic crisis, many Spanish physicians are giving services under contracts which grant them but small salaries. The condition of Spanish physicians has become worse as a result of free medical care given in several hospitals and clinics of public beneficence or official centers for the care of the poor. In these centers, physicians, as a rule, give their services free. The economic condition of the physicians in large cities is made worse by the fact that some members of the profession hold several positions. In studying the statistics, he found the following data: Among about 3,000 physicians practicing in Madrid, 400 have great prestige, a large clientele and most of the official and private positions, while the remaining 2,600 physicians are in bad economic condition. In Spain there are 1,000 inhabitants for each physician. These statements are of value, since they have been published in the *Boletín oficial del Colegio oficial de médicos de Madrid*. The profession hoped to see a more even distribution of the positions under the new governmental régime, but up to the present (with the exception of the lamentable expulsion of some members, such as Dr. Noguera, who was suspended from the direction of the Hospital de la Cruz Roja), all the positions are held by certain members. The medical profession has a sad outlook. Probably that is why the local members of the profession do not approve of the coming to Spain of the German physicians who recently suffered persecution in Germany, some of whom are already in Madrid. In view of the hospitality shown them by prominent members of the medical profession, it is believed that more German physicians will arrive in the near future. This is a difficult problem for the Spanish profession under the present circumstances. Some physicians favor the coming of German physicians, while others see in them competitors who have a well earned reputation and, some of them, even worldwide fame.

The Schilling Hemogram

Dr. Verdes Montenegro recently gave a series of lectures, at the Instituto Rubio, on the value of the Schilling hemogram in the detection of residual tuberculous lesions. A comparison

was made of the diagnostic value of the Arneth formula and the Schilling hemogram. The Arneth formula deals only with polymorphonuclear neutrophils, while the Schilling hemogram includes myelocytes, metamyelocytes, rod and segmental forms of neutrophils, basophils, eosinophils, lymphocytes and monocytes. Having used both methods for five years in the Instituto Rubio, he considers that in the detection of residual lesions of pulmonary tuberculosis the Schilling hemogram shows a sensitiveness that cannot be equaled by any other method of clinical investigation, including the roentgen examination. The activity of lesions in patients considered as cured, which is not detectable by any other clinical method, can be detected by the Schilling hemogram. The speaker showed hemograms and roentgenograms obtained from suspected tuberculous persons and commented on the results from both methods. He explained the significance of an increase or decrease of certain cells, such as lymphocytes and monocytes. The index of nuclear deviation is high in persons living in a tuberculous environment. It goes back to normal when the person moves from this environment. The association of nuclear deviation and neutrophilia is of clinical importance because it is generally observed in patients in whom the cure of tuberculosis seems to be permanent. The speaker explained the significance of the variations of the leukocytic formula and the increase of lymphocytes and monocytes in different forms of active tuberculosis because the normal hemogram in residual tuberculosis is an indication of the more or less lasting inactivity of the tuberculous foci.

Drug Addiction in Spain

Dr. Rodriguez Vera, a member of the National Board Against Toxicomania in Spain, recently lectured on the abuse of narcotics. He reported his observations on the influence exerted by drug addiction on the offspring. When the father is the addict, the children inherit a poor constitution with delayed growth and hyperexcitability of the nervous system. The muscular capacity is greatly diminished in those children; poor functions of alimentary assimilation and frequently infantile diarrhea are found. When the mother is the addict, the children as a rule die about three days after they are born. The fetal blood as well as the blood of the mother is saturated with toxic products. New-born infants of addict mothers are in a condition similar to that of an addict adult, without having the resistance of the adults. Some children in this group cannot suckle and cry from the time they are born until they die. As a rule they die in three or four days in convulsions. In 1932, Dr. Rodriguez Vera stated that 141 sellers of narcotics (morphine, cocaine, diacetylmorphine and others) were detected by the authorities. Sixty pharmacists have been prosecuted for smuggling narcotics. A list of all the convict addicts has been made, which contains more than 2,000 names. The daily press reported recently the case of two shoe-blacks who were carried to a first aid station because they were intoxicated. While they were not being watched, they stole all the narcotics at the station. This and other like cases show the prevalence of drug addiction in Madrid.

Deaths

Dr. Sanchiz Banús, president of the School of Medicine of Madrid and psychiatrist of the Beneficencia Provincial of Madrid, died unexpectedly. He was a deputy of the house of representatives, elected by the socialistic party. He was an exponent of modern psychiatric theories. Dr. Sanchiz Banús was not rich; his family should be helped by the socialistic group, to which he gave great support.

Dr. L. Lopez García, a prominent histologist of Valladolid, who had retired, because of his age, died. For years he was a professor of pathologic histology. Such prominent histologists as Drs. Perrin of Mexico and del Rio Ortega of Madrid were his pupils.

May 6, 1933.

Pensions for Aged and Incapacitated Physicians

In Rumania, until now, the National Medical Association has been the only organization that has helped distressed physicians, which it has done by means of modest financial support. The association distributed from 1922 to 1932 a total of 318,900 lei, in amounts varying from 500 to 5,000 lei. Under the present circumstances, when general distress has ruined even the best of medical practices, the distribution of such small sums is ridiculous. The distribution of alms that are not only insufficient but humiliating must be given up and a pension system of permanent character established.

The economic crisis in the Rumanian medical profession affects all physicians. Searching for the causes, aside from the general financial crisis, one finds two underlying factors: a lack of organization among physicians and an overproduction of physicians. The symptoms of poverty in the profession are being accentuated from day to day. There is a more restricted field for physicians wishing to practice, and competition becomes ever more severe. There are about 8,000 practitioners, of whom 2,000 are in Bucharest, which is too many in proportion to the population. Among such conditions, there is a need for old age and invalidity pensions for doctors. Not every European country can boast of such institutions. In Austria, where about 80 per cent of the population is on the panel, the following system has been introduced: All medical fees accruing from the treatment of panel patients are collected in a common office, and from this sum the necessary amount for the maintenance of the medical benevolent institutions is deducted. From this source a home for aged doctors has been erected in Upper Austria at a cost of about \$100,000.

In Denmark, obligatory old age insurance was attempted but proved unsuccessful. There are, however, two medical benevolent institutions: one for aged physicians, the other for the widows and orphans of doctors who have died without material means.

In Belgium there is a medical benevolent association, based on individual dues. Every doctor may become a member, if he pays the dues from his twenty-fifth year on. If he joins after this age, the fees have to be paid retrospectively.

In Liège, Belgium, there is a mutual benevolent office where members paying a fixed sum are entitled to a daily allowance in case of sickness. Also a group of doctors in Belgium contracted with an insurance company to pay a minimal yearly premium for insurance in case of death or permanent disability, amounting to 25,000 Belgian francs; this sum may be increased up to 100,000 francs. There is another well organized insurance company in Belgium, managed exclusively by physicians. This company insures its members against liabilities arising out of malpractice, accidents and other contingencies.

In Switzerland there is an old age pension institute whose membership is limited to physicians under 40 years of age who are healthy and are members of the national medical association. This institution operates independently a cooperative society, which grants loans to distressed members. There is also a medical benevolent society which, from the voluntary contributions of physicians and others, grants allowances to physicians who are incapacitated and to their relatives.

In Poland there is compulsory mutual insurance for all physicians of the country. In England, Germany, Yugoslavia and Greece there are as yet no similar organizations.

In Rumania, two methods are open: either to contract with an insurance company on highly advantageous terms or to establish an independent old age pension and invalidity organization. The government promised to aid with considerable money the latter plan, and the majority of Rumanian physi-

cians are in favor of it. The regulations have already been compiled and approved by the government. The income of this association will be derived from the following sources: The National Medical Association has donated 1,500,000 lei in stock. The income will originate from (1) the proceeds of the sale of prescription blanks (the pension office will issue prescription blanks, the use of which will be obligatory, a certain part of the sale price being allotted to the pension fund); (2) the registration fees paid by members; (3) various subsidies, donations, balls and concerts; (4) contributions by the medical chambers; (5) grants from the Rumanian Medical Association; (6) 0.5 per cent of the net income of all sanatoriums, private hospitals and radiographic laboratories.

To be entitled to a pension, a member must be 60 years of age and at least twenty years in medical practice, and have paid the member fees regularly. The widow of a member and the legitimate children of a deceased member, if they are under 18 years of age, also are eligible to receive assistance. This age limit is extended to 21 if the child is a university student. Any physician applying for an old age pension has to produce a certificate showing that he has been removed from the register of practitioners.

The chamber of deputies will discuss the bill in September and the pension association will begin functioning in October.

A New Law to Prevent Venereal Diseases

The *Monitorul Oficial*, the official gazette, published, March 3, the new law on the prevention of venereal diseases. The law prescribes that venereal diseases shall be treated only by qualified medical practitioners. All other persons commit the offense of quackery, if they treat such patients. All attending physicians have to make out a report, placed at their disposal by the magistrates, for every patient, registering the treatment given and the progress. If patients do not come regularly, the physician is obliged to report this to the magistrate, which places them under his control, and he may intern them in a hospital as long as they are infectious. A drastic feature of the law is that venereal patients, if they knowingly infect anybody, are liable to imprisonment from three months to one year. In cases of new infections, the physician is obliged to find the source of infection. Patients under legal age (21 and 18, respectively) have to be treated at the expense of the parents. Hospitals, polyclinics and village district physicians are obliged to treat all venereal patients free of charge, their bill to be paid by the state. Chemists who sell drugs to such patients without medical prescriptions commit the offense of quackery and will be prosecuted. Persons and institutions recommending or selling to such patients "miraculous" or "secret" medicines are liable to a fine ranging from 5,000 to 50,000 lei. Physicians must enlighten their patients on the consequences of spreading the disease. The ministry of public health provides all venereal specialists with instructions to be distributed among venereal patients. The law also contains paragraphs against secret prostitution.

Marriages

EDWARD BINNEY LANE, Boston, to Miss Ida Niles Southcombe of Jamaica Plain, Mass., May 31.

IRVING G. FUHR to Miss Henrietta Bearman, both of Brooklyn, March 19.

HUBERT A. BARGE to Miss Drucilla Albrest, both of Miami, Fla., June 1.

JOHN R. EGGLESTON, Decatur, Ala., to Miss Betty Brewer, March 10.

MEYER S. FOX to Miss Sylvia Meyer, both of Milwaukee, May 14.

Deaths

Alexander Brown Dancy, Jackson, Tenn.; University of Louisville (Ky.) School of Medicine, 1900; Vanderbilt University School of Medicine, Nashville Tenn., 1902; member of the Tennessee State Medical Association, and the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; president of the Mid-South Post Graduate Medical Association; councilor of the Eighth District, Tennessee State Medical Association; on the staffs of the Crook Sanatorium, Memorial Hospital and the Webb-Williamson Hospital; aged 54; died, June 10, of heart disease.

Frank Warren Langdon, Cincinnati; Miami Medical College, Cincinnati, 1881; chairman of the Section on Nervous and Mental Diseases, American Medical Association, 1902-1903; member of the American Psychiatric Association and the Association for Research in Nervous and Mental Diseases; emeritus professor of psychiatry, University of Cincinnati College of Medicine; past president of the Cincinnati Academy of Medicine and the Cincinnati Neurological Society; aged 80; died, June 9, of bronchopneumonia.

Claude Wallop Colonna * Surg., Lieut., Commander, U. S. Navy, retired, San Francisco; Medical College of Virginia, Richmond, 1917; fellow of the American College of Surgeons; entered the navy in 1917; served during the World War; retired in 1927 for incapacity resulting from an incident of service; aged 39; died, May 14, at the U. S. Naval Hospital, Mare Island, Calif., of chronic pulmonary tuberculosis.

Roland E. Loucks * Detroit; Medical Faculty of Trinity University, Toronto, 1903; fellow of the American College of Physicians; member of the Radiological Society of North America, American College of Radiology and the American Radium Society; owner of the Memorial Hospital; on the staffs of the Harper, Grace and Receiving hospitals; aged 63; died, June 5, of heart disease.

Thomas Teasdale Church * Salem, Ohio; Homeopathic Hospital College, Cleveland, 1882; member of the Associated Anesthetists of the United States and Canada; secretary of the Columbiana County Medical Society; city and county health officer; on the staff of the Salem City Hospital; aged 72; died suddenly, May 27, at the Cleveland (Ohio) Clinic Hospital, of cerebral embolism.

John Joseph Meany * Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; Fellow of the American College of Surgeons; attending surgeon to the West Suburban Hospital, Oak Park, Ill.; aged 54; died, June 7, of angina pectoris.

Theodore Martin Wiersen, Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1906; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; aged 55; died, June 1, of hemorrhage due to carcinoma of the stomach.

Louis Isidor Breitstein * San Francisco; University of California Medical Department, 1903; assistant clinical professor of obstetrics and gynecology at his alma mater; on the staff of the Mount Zion Hospital; aged 54; died, May 19, in Silver City, Nev., of heart disease.

Richard Cartwright, Salem, Ore.; Chicago Homeopathic Medical College, 1882; Willamette University Medical Department, Salem, 1898; Hahnemann Medical College and Hospital, Chicago, 1905; aged 81; died, May 14, of chronic myocarditis, arteriosclerosis and nephritis.

Charles Alonzo Dorr, Hingham, Mass.; Dartmouth Medical School, Hanover, 1878; member of the Massachusetts Medical Society; formerly member of the school committee and board of health; aged 82; died, May 27, of diabetes mellitus and myocarditis.

George Worth Bence, Greencastle, Ind.; University of Virginia Department of Medicine, Charlottesville, 1871; formerly member of the state legislature; for twenty-two years secretary of the county board of health; aged 86; died, June 1, of angina pectoris.

James H. Kennerly, Batesville, Ark.; University of Louisville (Ky.) School of Medicine, 1876; member of the Arkansas Medical Society; formerly county health officer and health officer of Batesville; aged 84; died, May 13, of nephritis and arteriosclerosis.

Benjamin F. Ochs * New York; College of Physicians and Surgeons, Medical Department of Columbia College, 1886;

* Indicates "Fellow" of the American Medical Association.

on the staffs of the Fordham Hospital and the Rockaway Beach (N. Y.) Hospital; aged 70; died, May 25, of coronary sclerosis.

Bernard Benjamin Harrison Aarons, Philadelphia; Medico-Chirurgical College of Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; police surgeon; aged 43; died, May 28, of a self-inflicted bullet wound.

Frank Irving Brown, South Portland, Maine; Medical School of Maine, Portland, 1891; member of the Maine Medical Association; for many years member of the school board; aged 73; died, May 28, of myocarditis and chronic myocarditis.

Jonathan Perry Wolf \oplus Evansville, Ind.; Medical College of Indiana, Indianapolis, 1905; member of the Associated Anesthetists of the United States and Canada; on the staff of St. Mary's Hospital; aged 57; died, June 1, of heart disease.

William H. Tucker, Bradner, Ohio; Ohio Medical University, Columbus, 1900; member of the Ohio State Medical Association; aged 64; died, May 27, in the Community Hospital, Fremont, of heart disease and diabetes mellitus.

Henry C. Lyman, Norwich, N. Y.; University of the City of New York Medical Department, 1872; member of the Medical Society of the State of New York; aged 85; died, May 26, of chronic interstitial nephritis.

Samuel A. Weisenberg \oplus Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1898; aged 56; died, May 17, of coronary sclerosis, angina pectoris and arteriosclerosis.

Charles Henry Colgate \oplus Rockland, Mass.; Boston University School of Medicine, 1901; served during the World War; aged 59; died, June 4, of heart disease, while trying to rescue a girl from drowning.

John Dexter Lyon \oplus Minneapolis; Northwestern University Medical School, Chicago, 1904; on the staffs of St. Barnabas Hospital and the Asbury Hospital; aged 58; died, May 29, of coronary disease.

Thomas B. Williams, South Euclid, Ohio; Western Reserve University Medical Department, Cleveland, 1882; member of the Ohio State Medical Association; aged 84; died, May 24, of myocarditis.

Jonathan Pearson, Niagara Falls, N. Y.; Albany Medical College, 1915; formerly member of the state board of health; served during the World War; aged 45; died, May 17, of cerebral hemorrhage.

David T. Martyn, Columbus, Neb.; Northwestern University Medical School, Chicago, 1869; member of the Nebraska State Medical Association; Civil War veteran; aged 87; died, April 28, of senility.

John W. Naylor, Cayce, Ky.; University of Louisville School of Medicine, 1887; for many years member of the county board of health; aged 67; died, May 7, of malignant tumor of the throat.

F. H. Robinson, Delphi, Ind.; Pulte Medical College, Cincinnati, 1881; member of the Indiana State Medical Association; formerly mayor of Delphi; aged 73; died suddenly, May 27, of heart disease.

Amzi Wallace Rudisill, Memphis, Tenn.; Memphis Hospital Medical College, 1891; member of the Tennessee State Medical Association; aged 64; died, May 11, of chronic nephritis and hypertension.

Earl Green \oplus Mount Vernon, Ill.; Bellevue Hospital Medical College, New York, 1884; aged 72; died, June 3, in the Mount Vernon Hospital, following a prostatectomy for prostatic hypertrophy.

Ernst G. Zimmer, Upland, Ind.; Cincinnati College of Medicine and Surgery, 1886; member of the Indiana State Medical Association; aged 75; died, May 30, of cerebral hemorrhage.

James Charles Haley, Buffalo; University of Buffalo School of Medicine, 1907; aged 53; died, May 23, in East Aurora, N. Y., of acute dilatation of the heart and mitral insufficiency.

James L. Ridgely, Baltimore; University of Maryland School of Medicine, Baltimore, 1888; for many years member of the city health department; aged 65; died, May 25, of myocarditis.

James Henry Jackson, Center Ridge, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1891; aged 73; died, May 13, in a hospital at Morrilton, of acute myocarditis.

Alfred Henry Albert Mayer \oplus Baltimore; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1887; aged 68; died, May 15, of carcinoma of the lung.

Conrad Georg, Sr. \oplus Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1872; formerly city health officer and coroner; aged 85; died, May 29, of arteriosclerosis.

William H. Merritt, Pleasantville, Iowa; College of Physicians and Surgeons, Keokuk, 1877; member of the Iowa State Medical Society; aged 81; died, May 31, of carcinoma of the stomach.

Elijah Robert Blalock, New Concord, Ky.; University of Louisville School of Medicine, 1905; member of the Kentucky State Medical Association; aged 54; died, May 23, of heart disease.

Eugene G. Regennas \oplus Hope, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1886; also a dentist; aged 80; died, May 26, of a tumor of the spleen and chronic cystitis.

William R. Vaupell, La Porte, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1894; aged 71; died, April 29, of multiple sclerosis.

John J. Baumann, Jersey City, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; aged 71; died, May 20, of Parkinson's disease.

Henry A. Wilson \oplus Bowdill, Ohio; Western University Faculty of Medicine, London, Ont., Canada, 1891; aged 66; died, June 1, of pleurisy and pneumonia, following an accident.

Golan Sampson Perry, Raleigh, N. C.; Howard University College of Medicine, Washington, D. C., 1918; aged 42; died, May 28, in St. Agnes' Hospital, of cerebral hemorrhage.

Arthur Linwood Brown \oplus Winchester, Mass.; Tufts College Medical School, Boston, 1908; on the staff of the Winchester Hospital; aged 63; died, May 15, of heart disease.

Ira Morris Comstock \oplus New York Mills, N. Y.; University of the City of New York Medical Department, 1879; aged 77; died, May 10, of arteriosclerosis and nephritis.

George Hopkinson, Boston; Harvard University Medical School, Boston, 1905; member of the Massachusetts Medical Society; aged 59; died, May 26, of coronary thrombosis.

Tobe Turner Webb, Laynesville, Ky.; University of Louisville (Ky.) School of Medicine, 1909; aged 53; died suddenly, May 19, of cerebral hemorrhage and arteriosclerosis.

David R. Griffith, Creighton, Mo.; Kansas City Medical College, 1882; member of the Missouri State Medical Association; aged 79; died, March 22, of general debility.

James D. Smith, Benton, Ill.; American Medical College, St. Louis, 1879; member of the Illinois State Medical Society; aged 94; died, May 19, of an injury to the hip.

Julian O. Terrill, Wichita, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1882; aged 75; died, April 28, in a hospital at Topeka, of arteriosclerosis.

Charles Deletang Ebann, Cambridge, Mass.; Tufts College Medical School, Boston, 1894; aged 77; died, May 16, of chronic myocarditis and arteriosclerosis.

William H. Farrington, Raubsville, Pa.; Bellevue Hospital Medical College, New York, 1873; aged 84; died, May 18, of arteriosclerosis and bronchopneumonia.

John Martin Glover, Stapleton, Ga.; University of Georgia Medical Department, Augusta, 1887; aged 73; died, March 11, of cerebral and coronary thrombosis.

Andrew C. Enochs, Oklahoma City; Vanderbilt University School of Medicine, Nashville, Tenn., 1882; aged 74; died, May 17, of cerebral hemorrhage.

W. M. Brand, Springdale, Ark. (licensed, Arkansas, 1903); member of the Arkansas Medical Society; aged 50; died, May 15, of cerebral hemorrhage.

Edward John Ziegler, New Madison, Ohio; Rush Medical College, Chicago, 1882; aged 75; died, May 13, of chronic myocarditis and nephritis.

Andrew D. Steele, Perryville, Mo.; Washington University School of Medicine, St. Louis, 1896; aged 64; died, May 17, of angina pectoris.

Frank Douglas Davenport \oplus Winterset, Iowa; Eclectic Medical Institute, Cincinnati, 1887; aged 69; died, May 22, of angina pectoris.

Ira Bayard Hamblin \oplus Columbus, Ohio; Medical College of Ohio, Cincinnati, 1884; aged 76; died, May 25, of cerebral hemorrhage.

Eugen Le Sage, Medford, Wis.; Louisville (Ky.) Medical College, 1878; aged 85; died, May 11, of chronic myocarditis.

Schuyler O. Giffin, Columbus, Ohio; Medical College of Ohio, Cincinnati, 1886; aged 72; died, June 3, of heart disease.

Bureau of Investigation

THE "PATENT MEDICINE" BIG STICK

Are the Nostrum Makers Going Back to Their Old Tricks?

Those physicians who remember the evils of the nostrum traffic of thirty years ago will recall some of the methods used by the organized "patent medicine" interests to club newspapers into submission and to prevent, so far as possible, any information reaching the public that might be considered inimical to the "patent medicine" business. There was the notorious "red clause" which was part of so many "patent medicine" advertising contracts and which read:

"It is mutually agreed that this contract is void if any law is enacted by your state restricting or prohibiting the manufacture or sale of proprietary medicines."

There was the even more iniquitous clause in the advertising contracts which permitted the "patent medicine" concern to cancel its contract if any matter that nostrum makers considered detrimental to their interests was "permitted to appear in the reading columns or elsewhere" in the paper.

Following the publicity that was given to this "patent medicine" conspiracy against the freedom of the press, by Samuel Hopkins Adams' articles in *Collier's* and by the hundreds of thousands of reprints of those articles sent out by the American Medical Association, these clauses disappeared from "patent medicine" advertising contracts. It would appear, however, from a recent happening, that the nostrum interests are again up to their old tricks.

Dr. Stanley W. Sayer, District State Health Officer at Gouverneur, N. Y., recently delivered a short radio talk over Station WCAD at Canton, N. Y. The subject of the talk was "Patent Medicine Testimonials." The *Malone (N. Y.) Farmer*, published at Malone, N. Y., printed in full Dr. Sayer's radio talk. The radio talk started out with this statement:

"The reputable manufacturer of worth while products does not find it necessary to resort to extravagant ballyhoo. A good article can be sold on its real merits, or at least will not need continued high pressure salesmanship. It is well to beware of any medical preparation that is almost entirely recommended by testimonials."

Dr. Sayer then went on to call the attention of his hearers to the difference between the claims made in "patent medicine" advertising literature or in "patent medicine" radio broadcasts and the statements that are made on the trade package—the latter being subject to the penalties of the National Food and Drugs Act. He referred, also, to the "lurid testimonials" that are used by certain "patent medicine" concerns to bolster up the claims for their products; he referred to the "European specialists" and others of supposed financial or political standing who give testimonials. Dr. Sayer also referred to the notorious consumption cure that was declared a fraud some months ago in the federal courts, and recalled that it was brought out in that case that a testimonial had been given by a woman stating that she was cured of tuberculosis, when, as a matter of fact, she died of the disease, while the woman's son continued to reply to letters, confirming the statement of a cure and signing his mother's name. In closing his talk, Dr. Sayer emphasized the fact brought out by Samuel Hopkins Adams some years ago, that prospective buyers should ask three questions regarding every "patent medicine" testimonial: (1) Who gives it? (2) What does he say? (3) Why does he say it?

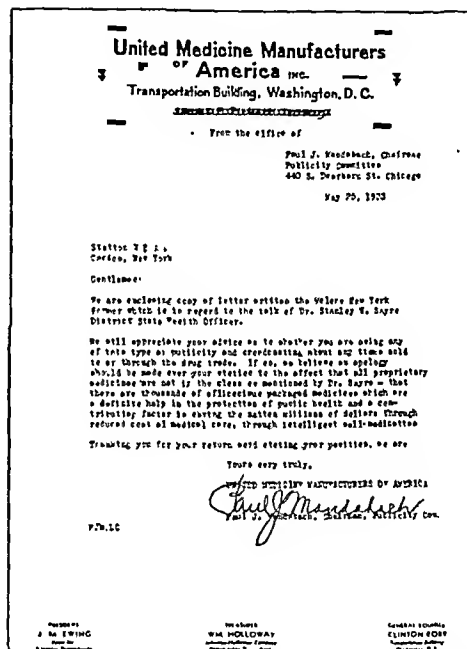

As already stated, this talk of Dr. Sayer's was published in full in the *Malone Farmer* for May 17, 1933. On May 25, 1933, the United Medicine Manufacturers of America, Inc., with offices at Washington, D. C., sent out two letters signed by Paul J. Mandabach, Chairman of their Publicity Committee, who has his headquarters in Chicago; one letter was to Station WCAD and the other letter went to the *Malone Farmer*. We reproduce in miniature Mr. Mandabach's letter to the radio station. It will be noted that Mr. Mandabach encloses with his

letter to the radio station a copy of his letter to the *Malone Farmer*. Mr. Mandabach goes on to state that if Station WCAD is broadcasting "any items sold to or through the drug trade," he believes that an apology should be made by the radio station to the effect that all proprietary medicines are not in the class mentioned by Dr. Sayer. As Dr. Sayer specifically prefixed his entire talk with a statement that made it clear that he was referring, not to "the reputable manufacturer of worth-while products," but to the other kind, it would appear that Mr. Mandabach was speaking in the interest of the other kind.

More interesting than the letter from the publicity man of the United Medicine Manufacturers of America, Inc., to the radio station is the letter from the same individual to the *Malone Farmer*. This letter read in part as follows:

"We note from clipping of your paper of Wednesday, May 17th, an article 'Patent Medicine Testimonials are Broadcast Topic.'

"As such publicity is detrimental to the reputable manufacturers as the article does not differentiate between the reputable manufacturers who are obeying the law and doing a real service for humanity and the type of manufacturer referred to, our organization resents this publicity and will appreciate your position hereon. . . ."

Photographic facsimile (greatly reduced) of a letter written by the publicity department of the United Medicine Manufacturers of America, Inc., to radio station WCAD, following a public health talk given by a state health officer on "patent medicine" testimonials of a disreputable kind.

Then follow two paragraphs in which it is stated that there are doctors who are unethical and calling attention to a recent newspaper report of a woman who was accusing a surgeon and a hospital of leaving a piece of gauze in her abdomen. It then closes with this statement:

"If you are printing any medicine advertising, or if you want any in the future [Italics ours.—Ed.], we believe that the square shooting manufacturers of proprietary medicines are entitled to an apology in your columns, stating that said article does not refer to all medicines but only to a few."

The threat contained in the paragraph just quoted is obvious. The implication is inescapable that if the *Malone Farmer* is carrying any "patent medicine" advertising or wants to carry any in the future, it should see to it, in the words of the old "patent medicine" advertising contract, that nothing "is permitted to appear in the reading columns or elsewhere in this paper" that may tend to awaken a public distrust in "patent medicines." Just what "patent medicine" concerns are members of the United Medicine Manufacturers of America, Inc., we do not know. We do know that last November Columbus, Ohio, newspapers carried a report that the Board of Managers

of the United Medicine Manufacturers of America, Inc., had met in that city and listed among those attending the meeting the following:

- "Warren Burgess, President of the *Kuor Company*, Kansas City, Mo.
"William Holloway, President of the *Johnston-Holloway Company*, Philadelphia.
"I. R. Blackburn, President of the *Blackburn Products Company*, Dayton, Ohio.
"K. D. Muir of the *Muir Laboratories*, Grand Rapids, Mich.
"Fred C. Arner, President of the *Arner Company*, Buffalo, N. Y.
"J. B. Van Dyke, President of the *Van Dyke Chemical Company*, Philadelphia.
"Dr. Eugene L. Maines of the *Smith, Kline and French Laboratories*, Philadelphia.
"John P. Nicodemus of the *Flazo Company*, Saginaw, Mich."

It would be interesting to know whether these gentlemen and the companies that they represent consider themselves "reputable manufacturers of worth while products" to which Dr. Sayer implied that he was *not* referring, or manufacturers who do use "lurid testimonials" and whose products are sold under claims that appear in the collateral advertising that do not appear on or in the trade package.

Correspondence

APOMORPHINE AS AN ANTIDOTE TO STRYCHNINE POISONING

To the Editor:—In THE JOURNAL, May 20, page 1589, appeared an article by David and Harry Gold, entitled "Apomorphine as an Antidote to Strychnine Poisoning," in which several references were made to a paper by us (THE JOURNAL, April 2, 1932, p. 1133). The authors take exception to our experiments showing that apomorphine tends to counteract the effects of strychnine in doses somewhat less than twice the lethal. In our paper we pointed out clearly that apomorphine is not a true antagonist to strychnine and recommended in strychnine poisoning the much more effective and true antidote phenobarbital sodium. But our demonstration of the superiority of the barbiturates to apomorphine and the further demonstration of the ineffectiveness of magnesium sulphate does not alter the validity of our experiments on apomorphine. The barbiturates, as has been fully confirmed, save life, after administration of approximately five times the lethal dose of strychnine; apomorphine, on the contrary, saves only after approximately twice the lethal amount of strychnine, a fact which we clearly demonstrated with rats as the experimental animals.

Careful reading of the table presented by the Golds does not seem to us to invalidate our contentions. They administered to dogs 7 mg. of strychnine sulphate per kilogram. The dogs that did not receive apomorphine died. To six dogs they gave apomorphine as well as strychnine; two of the dogs lived.

It appears to us that the experiments of the Golds tend rather to support our conclusion than their own.

HOWARD W. HAGGARD, M.D.,
LEON A. GREENBERG, Ph.B.,
New Haven, Conn.

[The letter was referred to Dr. Gold, who replies:]

The defense by Haggard and Greenberg of their experiments with rats, with the barbiturates, and with magnesium is entirely beside the point because it has nothing to do with the substance of our paper. Our paper deals solely with the antagonism between apomorphine and strychnine which Haggard and Greenberg alleged applies to the dog.

Their conclusion regarding the effectiveness of apomorphine in protecting against more than a single fatal dose of strychnine in the dog is based only on the recovery of two dogs. This is hardly sufficient to justify the conclusion in regard to dogs,

irrespective of any support it may receive from experiments on rats.

The bald statements in their letter: "The dogs that did not receive apomorphine died. To six dogs they gave apomorphine as well as strychnine; two of the dogs lived," present as far as they go a statistical summary of our experiments, but it is incomplete and misleading. Four of the six dogs that received both drugs died without showing even a semblance of protection by apomorphine. A question of interpretation arose in the case of only one dog. We pointed out in our paper that in this case there seemed to be an antagonism between the two drugs, because the animal recovered from 0.7 mg. strychnine when given apomorphine as well and died from a similar dose of strychnine without the apomorphine subsequently, but that this interpretation was vitiated by the discovery in another case that a dog may recover from 0.7 mg. strychnine and die from a similar dose at another time even though it received apomorphine in both instances.

Their statement that "the experiments of the Golds tend rather to support our conclusion than their own" is therefore based on the recovery of only one dog under the circumstances stated. Further comment about this seems hardly necessary.

Their letter refers to "7 mg." of strychnine. That, in our paper, is 0.7 mg.

HARRY GOLD, New York.

PERMANENT ENLARGEMENT OF THE LIPS AND FACE

To the Editor:—Referring to the communication by Dr. Pusey (THE JOURNAL, May 20, p. 1626), I feel that I should reply, for it is apparent that Dr. Pusey failed to recognize the entity that Dr. Kirch and I described (THE JOURNAL, April 22, p. 1230).

The condition to which Dr. Pusey referred, and which is secondary to erysipelas and lymphangitis, is indeed well known to the medical profession in general, and to Dr. Kirch and me, for we have seen many such cases at the Mayo Clinic.

We have given surgical treatment for the condition which we described, and the fact that the responsibility for the results of such treatment would rest directly on us has made us particularly careful to exclude cases in which the condition had originated with erysipelas or lymphangitis. Nevertheless, we have not been so self confident as to proceed to surgical treatment without having first obtained the opinion of the dermatologists and, in the cases of facial palsy, of the neurologists. There has been the closest cooperation in consultation, and accord in diagnosis, among us, Dr. O'Leary of the Section on Dermatology, and Dr. Shelden of the Section on Neurology. Dr. Shelden presented the neurologic features of this entity at the meeting of the American Neurological Association, May 8, at Washington, D. C.

Obviously, our evidence need not all be given again in this note. But if the entity has once been seen it can be identified again by the typical history, which is similar in some respects to that of angioneurotic edema and distinctly different in other respects, by the course of the disease, by the soft residual enlargement, and by the facial paralysis. These features make the condition we described readily distinguishable from the swelling of the face produced by inflammatory causes. We know of no case of swelling of the face, of the types under discussion, consequent to an inflammatory disease, in which there has been facial paralysis.

Results of treatment in the condition we described have been good, whereas results of treatment of enlargements of the face caused by erysipelas and lymphangitis, according to both Dr. Pusey and Dr. O'Leary, are less satisfactory.

Our cases have been carefully selected over a period of twenty-two years with the cooperation of the members of the

staff we have named, as well as with others, and since Dr. Pusey did not cite any literature with which we are unacquainted, we cannot but adhere to the conviction that we have added another type of permanent enlargement of the lips and face to those which the members of the medical profession have recognized for many years, and that we have demonstrated an efficient treatment for it.

GORDON B. NEW, M.D., Rochester, Minn.

[A copy of Dr. New's letter was sent to Dr. Pusey, who replies:]

To the Editor:—I am still unconvinced. The cases which Dr. New produces, excepting only the minor number accompanied by facial palsy, are indistinguishable by any points that he has brought out in either of his communications from the solid edema described by Hutchinson fifty years ago. Nowhere has he indicated any consideration of previous literature on the subject, except to say that he is not unacquainted with it. If he is going to establish his condition as a new entity he should show wherein the new one differs from that which will occur to all those familiar with the subject when he reads the paper. He has not yet attempted even to prove his case. It cannot be accepted on the *ex cathedra* statement that it is different. I still think that he is dealing with Hutchinson's solid edema of the face.

WILLIAM ALLEN PUSEY, M.D., Chicago.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VITAMIN D MILK

To the Editor:—Can you inform me about the use, preparation and dependability of vitamin D milk? Is it a satisfactory substitute for cod liver oil?

M.D., Connecticut.

ANSWER.—Vitamin D is the food factor that promotes the proper assimilation of calcium and phosphorus, the two inorganic constituents of bone. Therefore it is often called the antirachitic vitamin. It has been designated the "sunshine vitamin" because its effects are comparable, as an antirachitic, to those of exposure to the sun's rays or corresponding ultraviolet radiation. The need of vitamin D is greatest during the period of childhood. Recent studies on dental caries, though far from convincing, have raised the question whether the rôle of vitamin D in the protection of the teeth may not bring it into significance in the nutrition of adults as well as of children.

The widespread occurrence of rickets under conditions of living in temperate climates has emphasized the need of better prophylactic and curative measures. Hence it has become customary to attempt to insure proper antirachitic effects by supplementing the usual diet with potent sources of vitamin D or its equivalent in exposure to ultraviolet rays. As milk is the dominant food of the young, effort has been made to enhance the antirachitic potency of nature's "most nearly perfect food" in various ways. This has created much interest among dairymen as well as physicians and even the general public.

A recent publication of the Ohio Agricultural Experiment Station at Wooster (*Bimonthly Bulletin*, 18, May-June, 1933) summarizes the current methods of producing vitamin D milk: (1) by feeding irradiated yeast to cows, (2) by adding a cod liver oil concentrate directly to milk, (3) by irradiating milk (that is, subjecting it to ultraviolet rays). The first method has been in use for the longest time and consequently its use is spread over a larger area than is either of the other two methods. Use of the second method is steadily increasing, whereas irradiated liquid milk is just beginning to appear on the market. Various "brands" of vitamin D milk have already been accepted for recognition by the Committee on Foods of the American Medical Association. The Ohio bulletin, by Drs. Krauss and Bethke, presents the present status of the subject:

The production of vitamin D milk by the irradiated yeast method is accomplished by feeding cows irradiated yeast. The

amount of yeast fed daily is based on the production of the cows. The yeast may be fed to each cow separately or it may be included in the regular grain mixture. Milk from cows fed the proper amount of irradiated yeast will contain about 160 Steenbock rat units of vitamin D per quart of 4 per cent milk. Such milk has been fed to children and has been found to be effective in preventing or curing rickets. The chief advantage of this system of producing vitamin D milk lies in the fact that when the milk leaves the cow it contains the required amount of vitamin D and no further "tampering" is needed. One disadvantage of this method is that there is no assurance that the yeast will be fed faithfully from day to day. The chief disadvantage of this method lies in its inefficiency. Only a small percentage of the total number of rat units of vitamin D fed to the cows is recovered in the milk.

The addition of concentrates containing vitamin D consists in adding a prescribed amount of specially prepared concentrate, so that the resulting product contains about 150 Steenbock rat units of vitamin D per quart. The greatest advantage of this system lies in its efficiency. There is no waste, and a large amount of milk can be treated at one time in the milk plant. One disadvantage is that there is no assurance that the correct amount of supplement has been added to the milk. Another disadvantage of this method is psychologic. The fact that something has been added to the milk after it was produced does not lend itself well to sales appeal.

It is now possible to impart a potency of 50 Steenbock rat units per quart to milk by irradiation, without affecting the taste or destroying any of the nutritive properties of the milk. This is accomplished by exposing for a few seconds a very thin film of milk to the rays from flaming carbon arc lamps. Milk so treated has been shown clinically to be effective in the treatment of rickets. Specially built apparatus is employed, the nature of the set-up being varied according to the needs of the particular situation. The advantage of this method lies chiefly in the ultimate low cost per quart of milk. The method has the further advantage of eliminating to a greater extent the human element of error that enters into the other two methods. The amount of radiant energy imparted to the milk can be accurately recorded by means of ultraviolet ray meters, which may be used in much the same capacity as recording thermometers are used in pasteurization.

The general conclusions of the Ohio experts are important: "Assuming that the principle of vitamin D milk is sound and that satisfactory methods for producing such milk are now available, there remains the problem of control. What assurance does the consumer have that the milk purchased as vitamin D milk contains the specified amount of vitamin D? To determine the amount of this factor in a given sample of milk is a laborious and time-consuming procedure. A given plant could hardly afford to have its milk assayed for vitamin D more than once a month and small producers would find even this an expensive procedure. Unfortunately, no reliable chemical methods are yet available for determining the amount of vitamin D in foods. Assurance that the milk will measure up from day to day to the standards set must rest largely on confidence in those responsible for vitamin D milk production. Careful selection of licensees, reasonable supervision, and frequent assays should also be expected."

DANGERS TO HEALTH FROM CRESOL FUMES

To the Editor:—I should like to have the opinion of your research department as to whether or not the fumes from hot cresol and tricresyl phosphate would be injurious to the health of any one working in this mixture, whether or not the worker would be injured by the vapor coming off from a heated tank of 35 per cent cresol and 65 per cent tricresyl phosphate, and whether there would be any toxic effect if the worker got this on the skin. Of course, I know that the physiologic action is much the same as that of phenol and that the tricresyl phosphate caused what is known as ginger paralysis in the West and South in 1930-1931, so there is no doubt about its effect if taken internally; but what I want to know is whether workers could be injured from inhaling the vapor of the hot cresol or could absorb it through the skin in sufficient quantities to cause poisoning. Do you know whether investigation has been made with hot cresol along this line?

WILLIAM L. TRACY, M.D., Pittsfield, Mass.

ANSWER.—The cresols, like phenol, are readily absorbed from the intact skin and all mucous membranes. The boiling point of the cresols ranges from about 190 to 200 C. Chronic cresol poisoning from the continuous absorption of its vapors is possible if the temperature is high enough to cause its volatilization.

Technical tricresyl phosphate, which is usually a mixture of the ortho, meta and para isomers, is a relatively nonvolatile substance. The ortho and meta isomers boil at about 220 to 230 C. at much reduced pressure. At atmospheric pressure they decompose before boiling. Poisoning from tricresyl phosphate

as such through absorption of its vapors is therefore unlikely. Tricresyl phosphate poisoning through absorption of the ortho isomer from the skin, however, is possible, as this has recently been shown in animals by E. Gross and A. Grosse (*Arch. f. exper. Path. u. Pharmacol.* 168:473, 1932).

WEIGHT BEARING AFTER FRACTURE OF ASTRAGALUS

To the Editor:—I should like to know when to begin active and passive motion and when to allow weight bearing in a fracture of the astragalus of the left foot. Please omit name. M.D., New York.

ANSWER.—It is impossible to state in number of days or weeks when it is permissible to allow weight bearing in fracture of the astragalus. One must be guided by the type of fracture, the degree of reduction and the general condition of the foot and ankle.

A simple test of the efficiency of this foot can be made by allowing the patient to be on crutches with the affected foot protected. Before weight bearing is permitted, the patient should be allowed simply to touch the foot to the floor and "feel out" his ability to bear weight. All these patients should have protected weight bearing, using a cast or brace, and at a later date a proper shoe with a support that is rigid at first and later changed to a resilient one.

Just as soon as massage and active motions are not attended by unusual risk of displacing fragments, they should be started; at the same time, contrast applications of warm and cool sprays should be prescribed.

In cases of fracture of the astragalus, there is danger of developing traumatic arthritis involving the ankle joint and the subastragalar joint. For these reasons, motion should be instituted as early as is consistent with local conditions. It is important to mold the fragments and mold the ankle to its normal contours. The astragalus is a bone that occupies a unique position in the foot in that it is the mortise bone at the ankle. It has the entire superincumbent weight of the body, it is involved in flexion, dorsiflexion and plantar flexion, and it has no muscles attached to it.

The astragalus articulates with the tibia, fibula and scaphoid and with the os calcis in three places; it cannot move itself because it has no muscle attachments; it is subjected to more superincumbent weight than any other bone in the body.

If the astragalus is tilted, there is danger of varus or valgus foot, which may cause considerable trouble.

CALCIFICATION OF AURICLE

To the Editor:—What has been determined as the cause of calcification of the auricle in a young adult? What treatment is advised? Is it due to some endocrine disturbance? M.D., Milwaukee.

ANSWER.—Calcification of the auricle in a young adult is rare; it is generally the result of an extension of a chronic pericarditis into the tissue of the wall of the heart. In such cases the lime salts may be laid down both in the pericardium and in the heart itself. The most common causes of such pericarditis are (1) tuberculous infection and (2) massive involvement of the pleura and pericardium in the form of mediastinopericarditis, which may be associated with a severe pneumonia. Myocardial and endocardial lesions themselves may be the sites for the deposition of calcium, but of course most of the calcium resulting from endocarditis is found at the aortic or mitral valve, while in the myocardium infarction is the chief cause, located in the ventricles most commonly. J. G. Mönckeberg (in Henke and Lubarsch's *Handbuch der speziellen pathologischen Anatomie und Histologie*, vol. II, pp. 406-409) gives an interesting description of the two types of myocardial calcification, that laid down in previously damaged muscle and that called calcium metastases, in which a disorder of calcium metabolism is responsible primarily. He does not specifically mention calcification of the auricle.

The rare condition of hyperparathyroidism is associated with hypercalcemia and a tendency to deposition of calcium in the tissues. Wilhelm Hueper (*Arch. Path.* 3:14 [Jan.] 1927) reported metastatic calcification in various organs, including the heart muscle, experimentally in dogs on the administration of parathyroid extract. An interesting article by A. W. Ham (*Mechanism of Calcification in the Heart and Aorta in Hypervitaminosis D*, *Arch. Path.* 14:613 [Nov.] 1932) states that "enormous single doses of irradiated ergosterol will produce massive calcifications in the aorta, coronary vessels and cardiac musculature of the rat as soon as forty-eight hours after administration. Sections from the tissues twenty-four hours after administration show nothing that would presage such an imminent catastrophe, so that the calcifications do not appear

to depend on degenerative changes in the recipient tissues. On the other hand, the rapidity of formation, together with the massiveness of the calcifications, suggests very strongly that the prime factor in their causation is the inability of the serum to retain all its calcium in solution. It is suggested that precipitation depends on saturation of the serum with diffusible calcium plus other factors"—such as change in carbon dioxide tension and addition of other ions which would force a precipitation of calcium salts. "A marked inflammatory cell infiltration developed about the affected coronary vessels and about the calcified areas of cardiac muscle."

Calcification of the auricle may be encountered in cases of massive chronic pericarditis or in the mitral valve and its attachments in long standing mitral stenosis.

If there is evidence of a constricting pericarditis with calcification producing the symptoms of Pick's disease in a young adult, operation to resect some of the constricting adhesions may be indicated in favorable cases.

DANISH OINTMENT—POLYSULPHIDE-ZINC OXIDE COMPOUND OINTMENT

To the Editor:—Will you kindly advise me what the prescription of Danish Ointment consists of? M.D., Oregon.

To the Editor:—Will you please inform us as to whether a preparation known as "Danish Ointment" is listed in New and Nonofficial Remedies. If so, kindly let us know the formula so that the therapeutic value of this preparation may be determined by our medical staff.

ASSISTANT SUPERINTENDENT, Hospital, New York.

To the Editor:—Please inform me where I can secure "Danish Ointment," as I have two patients who have acne rosacea and are very anxious to get relief. I notice in *THE JOURNAL* that it is recommended for either rosacea or vulgaris. M.D., New Mexico.

ANSWER.—"Danish Ointment" is an unfortunately unscientific name for a potassium polysulphide-zinc oxide compound ointment described several years ago in connection with an article on "the Danish treatment" (*THE JOURNAL*, Feb. 9, 1924, p. 466). The directions for the preparation of this ointment are as follows:

1. One kilogram of sublimed sulphur is mixed with 2 Kg. of 50 per cent solution of potassium hydroxide. Gentle heat is applied until reaction ceases and the solution becomes clear. A slight excess of sulphur may be present.

2. Petrolatum, 225 Gm., is mixed with wool fat, 225 Gm., without heat.

3. To the ointment base is added 375 Gm. of the polysulphide solution mentioned in 1.

4. To 40 Gm. of 20 per cent sodium hydroxide solution is added 28 Gm. of zinc sulphate. The mixture is agitated thoroughly until reaction ceases, poured on filter paper, and washed thoroughly; then the washed precipitate is added to the foregoing.

5. Liquid petrolatum is added to obtain a total weight of 1,000 Gm.

6. Five grams of oil of bitter almond is added to check the somewhat disagreeable sulphide odor.

VACCINATION AGAINST TYPHOID

To the Editor:—During an epidemic of typhoid, it seems customary to give prophylactic vaccination against the disease to all those who have been exposed. I have given it myself. 1. Isn't it true that the body's resistance is lowered immediately after such injections? 2. Isn't it about two or three months before one may expect protection? 3. Is there any danger of precipitating symptoms in one already infected or increasing the severity of the disease in such a person by wholesale inoculation? 4. Is there any disadvantage or contraindication to giving the "shots" at intervals of one or two days instead of the usual week or ten days? Please omit name. M.D., Louisiana.

ANSWER.—1. There is no direct evidence that this is the case, and it is generally held at present that no undesirable "negative phase" develops.

2. While the individual response varies, one can expect the protection obtained to be in effect before two or three months. If the agglutinin titer of the serum is taken as an indication of the speed of cellular sensitization, the response can be considered to begin in a few days. Quantitatively, for maximum immunization, a somewhat longer period with repeated doses is, of course, necessary.

3. No danger seems to result from such a possibility. Some workers report the advantageous use of typhoid vaccines during the incubation period, but such an effect may be nonspecific in character.

4. It is generally thought that the optimal response to as few as three injections is obtained with intervals of from seven to ten days.

GAUCHER'S DISEASE

To the Editor:—Is it possible to make a definite diagnosis of Gaucher's disease from a biopsy of liver taken during laparotomy? If so, how? Please omit name.

M.D., New York.

ANSWER.—Yes, Gaucher's disease may be recognized on microscopic examination of tissue taken from the liver during life. There is increase in the interlobular connective tissue in which lie peculiar large cells. The typical Gaucher cell is from 20 to 40 microns in diameter but may be elongated; it has one or more small nuclei, frequently eccentric; the cytoplasm is faintly acidophilic, apparently foamy or wrinkled, and contains iron but not fat or lipoids. These cells may extend into the lobule and may be found in the sinusoids of the liver as well as in the branches of the portal vein. In addition to single large cells there may be found also fused cellular masses with many nuclei. In short, the microscopic changes in the liver in Gaucher's disease are characteristic and distinctive.

ATROPHIC RHINITIS

To the Editor:—Please advise me of the latest methods of lessening and combating the odor in atrophic rhinitis. Please omit name.

M.D., Ohio.

ANSWER.—After all crusts and secretions have been removed by means of cotton tampons, either dry or moistened with hydrogen peroxide, the use of irrigations with glucose solution will often reduce the odor. Glucose may be used in the form of corn syrup, a tablespoonful to the pint of water. A 25 per cent solution of glucose in glycerin may also be used, a few drops being instilled in the nose four or five times a day. Lessening the air space in the nose and thus preventing the rapid drying of secretions may be effected by the transplantation of ivory submucously into the septum. Some men do the Lautenschlager or Halle operations, which aim at mobilizing the lateral wall of the antrum and bringing it medially as far as possible.

EPSTEIN'S MICROSACCHARIMETER

To the Editor:—Will you kindly tell me whether the microscaccharimeter, according to Dr. Albert A. Epstein, is accurate enough for routine work. I am using this apparatus with, I think, good results. Please omit name and address.

M.D., North Dakota.

ANSWER.—The accurate use of any blood sugar method depends largely on the realization of the limitations of the method. With the Epstein microscaccharimeter it is particularly important to avoid reading colors that are too concentrated; i. e., readings on specimens of blood sugar that are too high for accurate determination without dilution. There are several more recent methods for blood sugar determination that are more accurate. The simplest way to determine whether work with the saccharimeter is satisfactory is to run some parallel determinations on the same specimens of blood with the saccharimeter and one of the more recent methods. If the error is within 10 per cent, the method should do for routine clinical work.

ALLISATIN "SANDOZ"—GARLIC

To the Editor:—Can you give me any information regarding Allisatin "Sandoz," put out by the Sandoz Chemical Works, Inc., of New York, distributed by E. Fougera & Co., Inc., of New York and advertised as a remedy for hypertension?

M.D., San Diego, Calif.

ANSWER.—According to the label, Allisatin tablets are stated to contain the equivalent of 15 grains of the fresh drug (garlic). In the advertising it is stated that Allisatin is "garlic specially treated with vegetal charcoal." Thus it would seem that Allisatin is not claimed to contain anything but some preparation of garlic.

The Sandoz Chemical Works, Inc., which markets Allisatin, has not requested an examination of the product by the Council and so far the product has not been reported on by the Council or examined in the A. M. A. Chemical Laboratory.

The use of garlic as a medicine, as well as a condiment, can be traced to earliest antiquity, and periodically it has been exploited for this or that condition. Some years ago the use of garlic had a revival first in France and later in England, and then proprietary preparations claimed to be derivatives of garlic were put on the market.

Preparations of garlic have not been shown to be of value, except perhaps as irritant expectorants with local action on the stomach. The medical profession of this country appears not to have been impressed with the reported value of garlic preparations.

BENEDICT'S METHOD OF ESTIMATING BLOOD SUGAR

To the Editor:—In Queries and Minor Notes (THE JOURNAL, February 18, p. 519) it is stated that the results of estimating the blood sugar with the Folin-Wu method (J. Biol. Chem. 41: 367 [March] 1920) average 22 mg. too high. Benedict's first method, which is the one I employ, is a modification of the Folin-Wu (J. Biol. Chem. 64: 207 [May] 1925); does it, also, render high results? If so, how much too high?

JANET R. WALLACE, Medical Laboratory Technician,
Rochester, N. Y.

ANSWER.—Benedict's first copper method (J. Biol. Chem. 64: 207 [May] 1925) gives blood sugar values that are too high in normal blood by about 6 or 7 mg. per hundred cubic centimeters of blood, to judge from Benedict's data. It would appear that Benedict felt that this method fell just short of giving the true sugar (dextrose) content of the blood. For this reason he described his second copper method (J. Biol. Chem. 76: 457 [Feb.] 1928), which yields results about 22 mg. lower than the Folin-Wu method (J. Biol. Chem. 41: 367 [March] 1920), this difference being equivalent to the value for the non-dextrose reducing substances present in blood. Benedict's latest description of the second copper method appeared in the *Journal of Biological Chemistry* in June 1931 (volume 92, page 141).

BLOODY DISCHARGE FROM NIPPLE

To the Editor:—Will you kindly state the significance of a condition characterized by the issue of a few drops of blood from the nipple in a woman about 60 years of age. There is no lump or induration anywhere in the breast, and no enlargement of the cervical or axillary or sub-clavicular lymph glands. No pain, tenderness or any other symptom is referable to the breast. The patient has mild diabetes, with the blood sugar average 150, and systolic blood pressure 180. Please omit name.

M.D., Pennsylvania.

ANSWER.—A bloody discharge from the nipple is an indication of the existence of a single duct papilloma, multiple duct papillomas, or duct carcinoma. Although the absence of a palpable tumor favors the presence of a benign lesion, the possibility of early duct carcinoma cannot be excluded. Transillumination of the breast would help in localizing the lesion and determining its single or multiple nature. The age of the patient is of some value in estimating the probability of the presence of duct carcinoma. The older the patient, the more chances of the lesion being carcinoma. If transillumination reveals a single opacity in the region of the nipple and areola, a wide local surgical excision should be considered and the necessity of further treatment would be determined by the microscopic appearance of the excised specimen.

CARBON DIOXIDE TENSION OF BLOOD

To the Editor:—Is it true or not that increase of carbon dioxide tension of the blood represents a shift toward the acid end of the equilibrium? A colleague says that increased carbon dioxide tension represents alkalinity and that in acidosis the carbon dioxide is diminished. Has he not confused carbon dioxide capacity (combining power), which is, I admit, reduced in acidosis, with the fact that the excess carbon dioxide has caused consequentially this reduced carbon dioxide capacity?

ISAAC APPERMAN, M.D., New York.

ANSWER.—Increase of carbon dioxide tension of the blood may represent a shift toward the acid end of the equilibrium, provided the carbon dioxide capacity of the blood has not increased coincidentally. The carbon dioxide combining power of the blood is a measure of the basic substances that are available in the balance against the carbonic acid. The correspondent's colleague, therefore, has undoubtedly confused carbon dioxide tension with carbon dioxide capacity. But even if one were to substitute "capacity" for "tension" in his statement, it would not necessarily be true unless the carbon dioxide tension did not increase coincidentally.

HARD WATER NOT RELATED TO NEPHRITIS

To the Editor:—Is it a recognized fact that unusual hardness of an alkali water is a common and predisposing factor in the causation of pyelitis, pyelonephritis or any combination of these conditions? Please discuss preventive measures especially with regard to the use of chemically softened waters. Also briefly enumerate treatment measures for cases of this condition caused in this manner. How would you advise one to proceed in the making of a survey in a locality of this kind with reference to the need of water treating improvements and the type of treatment required, especially if one could not muster other professional interest?

FRED E. DARGATZ, M.D., Kinsley, Kan.

ANSWER.—There is no good evidence to support the theory that unusual hardness of an alkali water is a predisposing factor in the causation of pyelitis or pyelonephritis.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

ALABAMA: Montgomery, July 11-14. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

AMERICAN BOARD FOR OPHTHALMIC EXAMINATIONS: Boston, Sept. 19. Application should be filed before August 1. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

CALIFORNIA: Regular. San Francisco, July 10-13 and Los Angeles, July 24-27. Reciprocity. Los Angeles, July 24. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: Regular. Hartford, July 11-12. Endorsement. Hartford, July 25. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homeopathic. New Haven, July 11. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

DISTRICT OF COLUMBIA: Washington, July 10-11. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

MASSACHUSETTS: Boston, July 11-13. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. The examinations will be held at centers where there are five or more candidates, Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 11-15. Sec., Mr. Charles D. Koch, 400 Education Bldg., Harrisburg.

RHODE ISLAND: Providence, July 6-7. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

SOUTH DAKOTA: Watertown, July 18. Dir., Dr. P. B. Jenkins, Pierre.

WASHINGTON: Basic Science. Seattle, July 13-14. Regular. Seattle, July 17-18. Dir., Mr. Harry C. Huse, Department of Licenses, Olympia.

WEST VIRGINIA: Charleston, July 11. Sec., Dr. Arthur E. McClue, State Health Department, Charleston.

New York January-February Examination

Mr. Herbert J. Hamilton, chief, Professional Examinations Bureau, reports the written examination held by the New York State Board of Medical Examiners in Albany, Buffalo, New York and Syracuse, Jan. 30-Feb. 2, 1933. The examination covered 9 subjects and included 10 questions. An average of 75 per cent was required to pass. Two hundred and two candidates were examined, 153 of whom passed and 49 failed. The following colleges were represented:

Book Notices

Manic-Depressive Psychosis: An Investigation of the Most Recent Advances. The Proceedings of the Association, New York, December 29th and 30th, 1930. Association for Research in Nervous and Mental Disease. Vol. XI of a Series of Research Publications. Cloth. Price, \$10. Pp. 851, with 59 illustrations. Baltimore: Williams & Wilkins Company, 1931.

This volume, the eleventh in a series of similar publications, contains thirty-six reports of research on the subject of manic-depressive psychosis. Each contribution appears as a chapter. Forty-six psychiatrists have been engaged in the researches reported and a board of three members has performed the editorial work. An interesting chapter by Dr. Jelliffe on the historical phases of the manic-depressive synthesis opens the book and the ethnological phase is touched on in the closing chapter on manic-depressive reactions in Negroes. Not only usual aspects of the subject, such as etiology, symptomatology, pathology and treatment, are considered in the intervening chapters but also, as might be expected in a research publication of this character, some of the less usual ones also. Among these are the affective psychoses of childhood, organic constitution of the cyclothymic, psychoneuroses allied to manic-depressive psychoses, psychoanalytic sidelights on manic-depressive psychosis, mechanisms of the manic-depressive-schizophrenic combinations, behavior charting in thymegasia, gastro-intestinal roentgenologic studies, and several physiochemical and metabolic studies. As the disease concept of manic-depressive psychosis is a symptomatic one, no surprise is occasioned by repeated statements, both by the contributors and by members of the commission who discussed the papers, as to the difficulty of finding "pure manic-depressive cases" for study. Patients with more or less typical attacks of manic-depressive psychosis showed "aloofness" of the schizoid type in the intervals even in some of the selected cases. As stated on its title page, the book is an investigation of the most recent advances in knowledge of manic-depressive psychosis. Its purpose is accomplished well. It is not to be expected that collected papers of this sort, no matter how well edited, will have the uniformity and coherence to be found in a well organized textbook. On the other hand, material that would have to be excluded from a textbook can be found here. Physicians especially interested in psychiatry will find the book of value.

History of Chinese Medicine: Being a Chronicle of Medical Happenings in China from Ancient Times to the Present Period. By K. Chinlin Wong, Licentiate of Medicine and Surgery, Hongkong, and Wu Lien-Teh, M.A., M.D., Dr.M.Sc., Director and Chief Medical Officer, Manchurian Plague Prevention Service. Cloth. Price, \$7.50; 30s. Pp. 706, with 104 illustrations. Tientsin: Tientsin Press, Ltd., [n. d.].

This history is published in commemoration of the twentieth anniversary of the Manchurian Plague Prevention Service, established in 1912 as a result of the devastating pneumonic plague epidemic of 1910-1911. It is really a union of two distinct works: book one, the history of the time-honored indigenous art, by Dr. K. C. Wong, lecturer on medical history of

the National University, Woosung, Shanghai, and book two, an account of the introduction and progress of Western medicine from the times of its introduction by the first foreign physicians who settled in China to the present day, by Dr. Wu Lien-teh, director of the Manchurian Plague Prevention Service.

Book one is divided into twenty-one chapters treating of three periods, the ancient Legendary Period (2697-1122 B. C.), the Historical or Golden Period (1121 B. C.-960 A. D.), and the Medieval or Controversial Period (961-1800 A. D.). Of these three periods the Golden one is of greatest scientific and medical interest. In it the great trio of famous ancient physicians achieved their fame, the "Nei Ching" or "Canon of Medicine" was written, the doctrine of the pulse was elaborated, and the philosophies of Taoism and Buddhism influenced the course of development of the underlying concepts of medicine and disease. Buddhism brought Indian influences into the indigenous art and practices of China.

Near the close of the Legendary Period (1140 B. C.) the Chou-Li directed that the duties of the sorcerer should be separated from those of the doctor, to whom were committed all matters related to medicine and the collection of drugs. The ancient Chinese ideograph for doctor contained the symbol for priest or sorcerer, but this was later changed to that for wine, thus indicating that the practice of medicine was no longer confined to the priests, who employed strong weapons to kill or drive away the demons of sickness, but was transferred to doctors, who administered strong elixirs to their patients. Medical practice of the Legendary Period was mainly made up of charms, plant lore, and psychotherapy.

The Golden Period was made famous by the philosophies of Lao Tzu, Confucius and Mencius. Their ideas changed medicine from a restricted practical art based on observation but shrouded in superstition, to pretentious systems of healing carried to absurd and extravagant extents. The study of medicine accordingly came to be dominated by the scholastic subtleties of visionary philosophies and by reverence for authorities. It crystallized into a rigid formalism and was elaborated into a fantastic excess of detail.

In this period the two controlling basic ideas of Chinese medicine were formulated. The first is the doctrine of the two principles Yin and Yang representing the male and female forces, the originators of all things. They are represented by Pa Kua or eight trigrams, and are the Chinese pattern of the doctrine of opposites. They pervade the whole of medicine. Thus, the skin is Yang and the interior is Yin. The heart and liver are Yang organs, and the spleen, lung and kidneys are Yin. Both diseases and their remedies fall into the Yang and Yin categories, and these relations determine treatment.

The second doctrine is that of the five elements, akin in its application to that of the four humors of the Greeks. These five, wood, fire, earth, metal and water, interact as generators and subjugators. They are related to five organs of the body, the spleen, liver, heart, lungs and kidneys, and to a complete system of thirteen factors, such as planet, color, climate, direction, number and sound.

The number lore of Pythagoras was surpassed in subtlety by that of the Chinese and flowered into complexity in medicine. There are three souls, four methods of diagnosis, five afflictions and sufferings, five kinds each of the various diseases and of injuries, six of weather, and seven of emotions. Multiples of seven regulate the life of woman and of eight that of man. The dual order of nature is reflected in the structure of man. He has four reservoirs for brain, air, blood and water to agree with the four seas, and 360 bones for the reason that there are that many degrees in the circle.

The Nei-Ching, or Canon of Medicine, was a summary of the experimental, anatomic and physiologic knowledge and the theoretical ideas of the centuries that had preceded it. It is characterized throughout by sophisticated subtleties, systematized by the two basic ideas noted. There was no concept of a nervous system; anatomic and physiologic ideas were formal and often false. Claims that Chinese physiologists anticipated Harvey's discovery of the circulation of the blood were not substantiated by experiment or confirmed by observation but were represented by general ideas, such as that "all blood is under the control of the heart" and "the blood current flows continuously in a circle and never stops."

Therapeutic measures were best represented practically by acupuncture, the technic, indications, prognosis and results of which were given in great detail. Venesection, cauterization, moxa, decoctions and massage were also described in general terms but without specific directions. The doctrine of the pulse was elaborated for the diagnosis and location of every kind of disease.

In the Chou dynasty medicine was highly organized, with superintendents of high grade doctors, dietitians and medical men of middle grade, and surgeons and veterinarians of lower grade. Classification was based on records of successes and failures.

That prevention was better than cure was clearly recognized by famous sayings, such as:

The sage does not treat those who are ill but those who are well. —*Su Wen*.

The good doctor pays constant attention to keeping people well so that there will be no sickness. —*Huai Nan-tzu*.

The skilful doctor treats those who are well but the inferior doctor treats those who are ill. —*Difficult Classics*.

The good physician first cures the disease of the nation, then human ailments. —*Ancient History*.

Personal hygiene and public health were recognized in directions for avoidance of spoiled foods and meats. Contamination of foods was recognized, exposure of foods on street stands was advised against, moderation and regularity in eating and drinking and temperance in all things were commended, brewing and distilling were forbidden, and avoidance of worry and venery was advised. Deep breathing and fresh air, physical culture, and the artistic avocations were commended. Prostitutes were segregated and hospitals of a low order provided for defectives.

It was in this period that Ts'ang (180 B. C.) wrote his analytic case histories, that Chang wrote his famous "Treatise on Typhoid" (168 A. D.), and that Hua T'o used narcotics and practiced abdominal surgery. Confucian dogma, which held that the body must not be mutilated, checked the progress of Chinese surgery and obliterated its early accomplishments.

Women were admitted to the medical profession in the Han dynasty (B. C. 206-320 A. D.), and the cultivation of drugs was established in the sixth century.

The Medieval Period (961-1800 A. D.) was one of intense specialism and the organization of medical schools, state examinations, and the growth of formalism. Teachers were held responsible for the attendance and progress of their pupils and were fined for their pupils' failures. The president was fined for the professors' lapses. Graduates were distributed in fixed ratios to the major specialties and appointed to prefectures and districts. The Ming dynasty was famous not only for its achievements in the arts but also for the Great Herbal (1578 A. D.), the classic of Chinese pharmacology, consisting of fifty-two volumes and comprehending a range of natural history comparable to that of the thirty-seven books of Pliny's *Historia Naturalis*. It is the best work on Chinese materia medica. It included not only such absurd and unsavory things as tiger bones and bat's dung but also valuable products recognized in modern medicine, such as kaolin, calomel, eumenol, chaulmoogra oil, and the recently rediscovered ephedrine.

Chinese medicine is responsible for the use of boiled water, well cooked meats, and the sewers of Peiping. It had a respectable body of sound information on midwifery, prenatal care, and women's diseases, and on the diseases of the eye. The major helminths of man were known. Tapeworm infestation was attributed to the use of raw meat. Leprosy, cholera, beriberi and syphilis were recognized. Castration was successfully performed, and a form of vaccination as a preventive of the dire effects of smallpox was introduced about 49 A. D. Powdered smallpox scabs were introduced in cotton plugs in the nose, and two kinds of cow fleas were known, but only the white ones were ground into powder and mixed with rice flour into pills.

Syphilis is reported to have been introduced in the Ming dynasty (1505 A. D.), and mercury was used in its treatment. It is evident from the earlier literature that the relations of chancre and syphilis were unknown and that constitutional syphilis was in earlier periods confused with leprosy.

Book two is contained in pages 125-706. It is an elaborate and detailed account of the extensive developments of Western

medicine and medical institutions, the rise of hospitals and medical schools, the growth of public health, and the operation of preventive medical measures. The large share in the organization of medical service and its social acceptance by the Chinese people as the result of medical missionaries is clearly brought out.

One feature of especial interest in the history of medicine in China is the work of Sir Patrick Manson, who served from 1871 to 1882 at Amoy as customs medical officer and in the Missionary Hospital. It was here that he came in contact with microfilaria in the blood and sought to establish its relationship to elephantiasis. These discoveries, added to those of Lewis in India, laid the foundations for the later scientific developments in the detection of other Haematozoa, notably of the malarial parasites, the trypanosomes and the spirochetes.

This book fills a unique place not only in the history of the art of medicine but also in the relation of that art to one of the oldest and most cultured civilizations of mankind. It is a contribution to the anthropology, folklore, philosophy and cultural history of a great people. It reveals an art founded in empiricism, encrusted with the increments of superstition, and maintained for milleniums by the aid of ancestor worship and a dominating respect for the past and for the classic writings of the fathers of the art. This art was not lacking in some features of great practical utility which modern scientific medicine is rediscovering and disentangling from their unessential increments.

The invasion of this entrenched body of ideas and practices by the sometimes none too certain and often not wholly coherent concepts of Western medicine is one of the most interesting phases of the history of civilizations. On a grand scale it is the conflict of the scientific method and modes of thinking of the modern age with a shrewd empiricism founded on practice with enough of the confirmation of results to carry the load of the unessential increments of superstition and profiteering with which custom had overlaid this ancient art in China. In this respect the book is one inciting much rereading and is provocative of meditation, both on account of the underlying philosophies and because of the revelations of the behavior of the human animal in face of the mysteries of disease and death. It is a book for the thoughtful practitioner, for the library of every medical school, university, learned society and medical missionary, and for the student of human culture, and is a prize for the book lover.

A Text-Book of Surgical Nursing. By Frederick E. Neef, B.Sc., M.L., M.D., Consulting Gynecologist, Lenox Hill Hospital, O. P. D., and Rockaway Beach Hospital, New York. Cloth. Price, \$2.25. Pp. 173, with 41 illustrations. Philadelphia: Lea & Febiger, 1933.

In sixteen short, well written chapters, the author covers the principles of surgery and the essentials a nurse needs for the foundation of her practical work in surgical nursing. After a short history of surgery and surgical nursing, only the subjects of importance are considered briefly and directly. Extensive descriptions of surgical disorders and details of nursing procedure are eliminated. Of particular value are the chapters dealing with the relation of the nurse to the patient before and after operation. These include the care of emergency cases, the nurse's duties in the operating room, special nursing measures after operation, and the recognition, prevention and treatment of complications. An unusual chapter in a nurse's textbook is one on radium in surgery, in which the principles and methods of its use are discussed. The book is well outlined, clearly and concisely written, and accurate to the point of being dogmatic at times. At the end of each chapter are good suggestions for classroom demonstration and suitable questions for review.

La tubercolosi del polmoni e delle pleure. Del Prof. Dott. Stefano Mancini, medico primario dell'Ospedale Civile di Livorno. Paper. Price, 50 marks. Pp. 1135, with 90 illustrations. Leipzig: Georg Thieme, 1933.

Here is truly an encyclopedic treatise on pulmonary and pleural tuberculosis. It has the rare merit of presenting an objective critical review of all the theories and hypotheses on the subject, unbiased by personal views. The subject is skillfully treated and the controversial theories are discussed. The author does not seem to be conversant with some of the work on the chemistry of tuberculosis and on the tuberculo-proteins that is being developed in America through cooperative research.

Ranke's doctrine on the clinical development of the disease and its division in the three stages is well presented with detailed discussion of the numerous objections that have been advanced against it. In chapter VIII the rôle of infections in the course of disease are carefully presented with the evidence tending to show that quite often the hypersensitive state prevails which renders the body hypersusceptible to the infection. The chapters on x-ray studies of the disease in all its stages and the clinical diagnosis of the disease in all its manifestations can be read with profit.

The surgical treatment of pulmonary tuberculosis is described in full detail. Pneumothorax and exeresis of the phrenic nerve are discussed, but there is a regrettable lack of statistical data. The medical, chemotherapeutic, and biologic treatment of tuberculosis is described profusely in several chapters.

The absence of statistical data and evaluation of the therapeutic agents mentioned is a disappointment. A large number of preparations of unknown composition are mentioned without any information on pharmacologic action, toxicity and therapeutic results in animals and man.

Morris' Human Anatomy: A Complete Systematic Treatise. Edited by C. M. Jackson, M.S., M.D., LL.D., Professor and Director of the Department of Anatomy, University of Minnesota. Ninth edition. Fabrikold. Price, \$10. Pp. 1481, with 1166 illustrations. Philadelphia: P. Blakiston's Son & Company, Inc., 1933.

This edition has been carefully and thoroughly revised, and some of the sections have been entirely rewritten because of the development of new material. There are 253 new plates, of which 92 are printed in color. Obsolete illustrations have been omitted. The preface points out that the nomenclature includes the latest contribution of the Nomenklatur-Kommission (NK) immediately after the BNA terms. There is a list of associate contributors who have been responsible for special sections of this work. Important facts are given in large type, followed by fine details in small type, with the use of boldface for names wherever they appear. The long record of usefulness of this book constitutes sufficient recommendation.

La gymnastique des tout petits. Par Doris Reichmann. Traduit de l'allemand par le Dr. P. Gauthier-Villars. Paper. Price, 20 francs. Pp. 57, with 71 illustrations. Paris: Librairie-Imprimerie Gauthier-Villars, 1933.

This little book is a French translation of the German work of Doris Reichmann. The book contains the outline of general observations and specific gymnastic movements for young normal children. It contains directions for twenty sessions of gentle passive movements in training an infant 4 months of age. The sessions vary from five to fifteen minutes in duration. The movements of the upper and lower extremity and trunk are illustrated by excellent photographic reproductions and line drawings. One is struck by the illustrations of remarkable child models. Not one of the children was able to walk.

A Companion to Manuals of Practical Anatomy. By E. B. Jamieson, M.D., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh. Third edition. Cloth. Price, \$5. Pp. 654. New York & London: Oxford University Press, 1932.

The first edition of this book, which appeared about twenty years ago, passed through six printings; the second, through three printings. The present edition is a hundred pages longer, because of advances in the knowledge of anatomy and to make the descriptions more readable. The book follows strictly the Basle anatomic nomenclature but inclines somewhat toward the use of English terms for certain words. It is an exceedingly practical, succinct outline of the manuals of practical anatomy used by most medical students in their dissections. The book is printed on good stock and fits easily into the coat pocket, despite the number of pages.

Ergebnisse der Enzymforschung. Herausgegeben von F. F. Nord und R. Weldenhausen. Bearbeitet von R. Ammon, A. Bertho, usw. Band II. Cloth. Price, 30 marks. Pp. 358, with 58 illustrations. Leipzig: Akademische Verlagsgesellschaft m. b. H., 1933.

The favorable reception accorded the first volume of the *Ergebnisse der Enzymforschung* has stimulated the preparation of a second volume bearing the same title. A similar plan of publication has been followed; namely, the collection of summarizing reports on various topics of enzyme research. The subjects discussed make this volume a valuable addition to

the one that appeared last year. The new subjects include the kinetics of enzyme reactions, cryolysis and its relation to the mechanism of enzyme action, the stereochemical specificity of esterases and the synthetic action of the ester splitting enzymes, the specificity of emulsin, the experimental basis of the enzymatic splitting of sugars, isolation and properties of crystalline trypsin, chemical reactions and energy relationships in the degradation and synthesis of carbohydrates and their split products, cozymase, the energy metabolism of the yeast cell, glycolysis, the mechanism of dehydrogenation, cytochrome and intracellular respiratory enzymes, peroxidase, blood coagulation, experimental enzyme systems, and the enzymatic function of mitochondria. An extensive author index is again included.

Syllabus of Medical History. By Victor Robinson, M.D., Professor of History of Medicine, Temple University School of Medicine, Philadelphia. Cloth. Price, \$1. Pp. 110, with illustrations. New York: Froben Press, 1933.

This is merely a compilation of a few questions and answers in the medical historical field. Its usefulness is obviously limited. It is intended, apparently, as a guide to teachers of medical history in developing their courses on the subject. However, the subject is in itself so individual that most teachers of medical history prefer to develop their own outlines and to teach according to their personal interests and the interests of their students.

Les maladies de l'énergie: Les asthénies et la neurasthénie. Par Albert Deschamps et Jean Vinchon. Fourth edition. Paper. Price, 40 francs. Pp. 423. Paris: Librairie Félix Alcan, 1932.

Written with the keen, logical analysis characteristic of the French clinician, this book offers a real contribution to an understanding of the mass of disorders that have been grouped under the general title of neurasthenia. The material is based on an intimate detailed observation of patients, coupled with a remarkably clear insight into the significance of the dynamic aspects of the organism; the presentation is strictly clinical. The view adopted in analysis is chemico-physical rather than psychoanalytic in a technical sense. From his observations, Deschamps was able to sort out at least some varieties and to lay down some rational indications for therapy. The book was awarded the Herpin prize of the French Academy of Medicine; the present edition has been prepared by Vinchon, who has retained most of the material originally included and has made some additions. The topic of energy of the body, with disorders in its production and distribution, is of universal medical interest; this book will well repay those who read it and can be recommended to physicians in general.

Observations of a General Practitioner. By William N. Macartney, M.D. Cloth. Price, \$3. Pp. 478. Boston: Richard G. Badger, 1932.

This is an autobiographical book of medical practice written by a practitioner of Fort Covington, New York. It is written in a rough and ready manner with numerous anecdotes. It discusses everything from domestic nursing, diet, pills and prescriptions to all sorts of diseases. There is a clinical index. One is inclined to doubt therapeutic knowledge which says that lobelia, grindelia, euphorbia pulifera and various herbal preparations are of service in treating asthma. Altogether the book offers a record of practical experience, but it is dispensed with a mass of verbiage.

Intracranial Tumors Roentgenologically Considered. By Loyal Davis, M.D., Ph.D., F.A.C.S., Professor of Surgery, Northwestern University Medical School. Volume XIV, Annals of Roentgenology: A Series of Monographic Atlases. Edited by James T. Case, M.D., Professor of Roentgenology, Northwestern University Medical School, Chicago. Cloth. Price, \$10. Pp. 277, with 135 illustrations. New York: Paul B. Hoeber, Inc., 1933.

The purpose of this volume is stated to be to emphasize the diagnostic and surgical importance of roentgenology in the treatment of intracranial tumors. This it proceeds to do as adequately as technical limitations will permit. In many of the plates, however, one sees the arrows but not what the arrows would indicate. Roentgenograms of the skull should always be stereoscopic, the anteroposterior as well as the lateral films. One should always be suspicious of convolutional digitations as an indication of intracranial tension when the sutures are not separated. The pituitary fossa is not always flat and saucer-like in secondary hydrocephalus, and a ballooned sella is not always pathognomonic of a pituitary adenoma.

In ventriculograms, the lighter air-shadow which lies lateral to the typical butterfly-wing is not the body of the ventricle but the flange of the anterior horn, which curves laterally over the head of the caudate nucleus. Many of the illustrations are superfluous and many of the clinical histories also, except in the chapters on encephalography and ventriculography, and do not aid in the comprehension of the text. The pathologic and clinical introduction to each chapter should prove useful to the roentgenologist and the book as a whole should be helpful to those who do not have direct access to such actual roentgenologic material.

Medicolegal

Abortion Due to Trauma.—The appellees, Bessie Hall and her husband, boarded the appellant's train at 11 a. m. About the time Mrs. Hall reached a seat and before she had time to sit down, the train started with a jerk. This caused Mrs. Hall to fall and strike her side against the arm of the seat. She was then about three months pregnant. The blow produced great abdominal pain and a hemorrhage from the genital organs, which continued until about 5 o'clock the following morning, when an abortion occurred. Mrs. Hall and her husband brought suit. On behalf of the defendant, a physician testified that in his opinion the abortion did not result from the injury, because the injury was not inflicted on the uterus and because sufficient time did not elapse between the time of the injury and the delivery of the fetus for the injury to have been the proximate cause of the abortion. A physician testifying for the plaintiffs said that in his opinion the injury might have caused the abortion. Judgment was given in favor of the plaintiffs, and the defendant railroad company appealed. Courts, said the Supreme Court of Arkansas, are not required to accept the opinions of expert witnesses as absolutely true and, regardless of all facts and circumstances in conflict with such opinions, to instruct verdicts based on the opinions of such witnesses. Expert witnesses themselves frequently differ in their conclusions and opinions in response to identical hypothetical questions, and hence their opinions do not rise to the level of physical facts. In this case, lay testimony tended to show that the injury was the direct cause of the abortion, and this was supported to a certain extent by the evidence of the physician who attended the injured woman at the time of the accident. There was, therefore, a conflict in the testimony, for determination by the jury and not by the court. And a directed verdict, which the defendant seems to have sought, was properly refused. The judgment of the trial court was affirmed.—*Missouri Pac. R. Co. v. Hall (Ark.)*, 53 S. W. (2d) 432.

Insurance: Misstatement by Insured in Application; Privileged Communications.—In executing an application for insurance, the applicant was asked, "Have you consulted a physician during the last five years?" To this he answered, "No." As a matter of fact he had been under treatment by a physician for two days for "a bilious attack and a bad cold" and had gone for treatment to a hospital maintained by his employer. It must be admitted, said the Supreme Court of Arkansas, that the representation made by the insured was a warranty, but even though the application contains a warranty, the power of the insurer's agent remains the same. When the agent is authorized to ask the question and to write the answer, and when he puts his own construction on facts of which he has knowledge and deduces from them an erroneous answer, which he writes down, his principal may be estopped from denying the correctness of the answer. When the applicant is acting in good faith and does not knowingly make a false answer as to facts on which the medical examiner may base his conclusion, he has a right to rely on the superior knowledge of the medical examiner. It would be a grave mistake to suppose that the rule which would avoid a contract for a false warranty could be extended so as to hold the applicant responsible for the truth of an answer which was the result of a mistake in judgment, or an error or a blunder, of the insurer's agent especially charged by the insurer with the preparation of the application.

The contract of insurance in this case stipulated that the insurance certificate should be held to be a contract made in the state of Ohio and subject to its laws. The insurer insisted that, under the decisions of the Ohio courts construing clauses in insurance policies similar to the policy before the court, the insured had waived his right to insist on secrecy under a statute providing for privileged communications between physician and patient. The insurer proffered, therefore, the evidence of physicians in attendance at the hospital where the insured had been under treatment before taking out his policy, to show his then physical condition and the diseases with which he was then afflicted. But, said the court, while the contract is by agreement of the parties to be construed as an Ohio contract, the laws of that state have no application except as to the determination of its meaning. The competency and admissibility of evidence are to be determined by the laws of the jurisdiction in which the case is tried—in the present instance, Arkansas. The Arkansas statute makes privileged the information which a physician or a trained nurse obtain while acting in a professional capacity, which is necessary to enable him or her to prescribe as a physician or to act as a trained nurse. A patient may waive the privilege by calling the physician as a witness or by a clause in the contract on which the suit is based. In the present instance, however, the contract contained no such clause, and the trial court properly refused to admit the proffered testimony of the physicians who treated the insured prior to the time when he made his application for insurance.—*Brotherhood of Railroad Trainmen v. Long (Ark.)*, 53 S. W. (2d) 433.

Workmen's Compensation Acts: Death Caused by Perforating Duodenal Ulcer.—A workman, in the course of his employment, stooped to pick up a toy trunk. While he was in the act of reaching down, and before he had picked up the trunk, he was attacked by a violent abdominal pain, which caused him to desist. He was immediately disabled and was taken home and later to a hospital. On the following day an operation showed a perforation of the duodenum, due to duodenal ulcers. The patient died of septic peritonitis caused by the perforation. His widow claimed compensation under the workmen's compensation act of Illinois. The circuit court set aside the order of the industrial commission, confirming an arbitrator's decision that the claimant was not entitled to compensation, and made an award in favor of the claimant. The employer appealed to the Supreme Court of Illinois. A claimant seeking compensation because of an employee's death, under the workmen's compensation act of Illinois, said the Supreme Court, must prove by direct and positive evidence, or by evidence from which the inference can fairly and reasonably be drawn, that death was caused by an accidental injury which not only occurred in the course of the deceased's employment but also arose out of his employment. Compensation may be awarded even though the deceased was suffering from a preexisting disease, if that disease is aggravated or its course accelerated by accidental injury, but the accidental injury must be the immediate or proximate cause of death. The finding of the industrial commission and of the arbitrator, said the Supreme Court, that in the present case the workman's employment was not the primary cause of his death and that his death did not arise out of such employment, was not contrary to the manifest weight of evidence. The judgment of the circuit court was therefore reversed and the decision of the industrial commission confirmed.—*Cruzan v. Industrial Commission (Ill.)*, 183 N. E. 334.

Malpractice: Nonunion of Fractured Femur Following Premature Departure from Hospital.—McHenry fractured his thigh bone near the hip and was removed to a hospital for treatment. A roentgenogram disclosed that the bone was shattered and that pieces of it extended into the flesh. After an unsuccessful attempt to get the fragments into place, an operation was performed, fragments of bone were removed, the fracture was set, and the limb was placed in a brace. When McHenry had been in the hospital about fourteen days, he decided to go home. His physician, one of the appellants, remonstrated and warned him of the danger of leaving so soon. The warning was of no effect. McHenry signed a statement by which he assumed all responsibility for the results and released all attendants from liability. The Thomas brace

in which the limb was being treated was removed, splints were put on, and relatives took McHenry home in a truck. When he arrived home, he removed the splints and placed his leg in a trough that he had constructed. A bad union resulted, and McHenry sued the physicians who had treated him. He contended that they erred in removing pieces of the fractured bone and predicated his case on the proposition that their removal was the absolute cause of the imperfect union. Judgment was given in his favor, and the physician-defendants appealed to the Supreme Court of Oklahoma.

In this case, said the Supreme Court, there was no special warranty of cure or special contract. There was only the implied contract that the defendants possessed that reasonable degree of learning, skill and experience which is ordinarily possessed by other members of the medical profession, that they would use reasonable care and diligence in the treatment of the case, and that they would use their best judgment in all cases of doubt as to the proper course of treatment. The evidence does not show that the physicians were lacking in qualification or experience. It does show that they used their best judgment in operating. If the patient had remained quiet, with proper splints on his leg, the chances of a good union would have been greatly increased. There was therefore, said the court, a failure of proof on the part of the patient to prove the necessary elements to support his complaint. The judgment of the court below was reversed and the case remanded with instruction to dismiss it.—*Muckleroy v. McHenry (Okla.)*, 16 P. (2d) 123.

Society Proceedings

COMING MEETINGS

American Association of Railway Surgeons, Chicago, August 10-12. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.
 Idaho State Medical Association, Yellowstone National Park, August 6-8. Dr. Harold W. Stone, 105 North Eighth Street, Boise, Secretary.
 Montana Medical Association of Anaconda, July 12-13. Dr. E. G. Balsam, Box 88, Billings, Secretary.
 Pacific Northwest Medical Association, Vancouver, B. C., July 4-7. Dr. C. W. Countryman, Paulson Medical Dental Building, Spokane, Wash., Executive Secretary.
 Western Branch Society, American Urological Association, Vancouver, B. C., August 3-5. Dr. George W. Hartman, 999 Sutter Street, San Francisco, Secretary.

MISSOURI STATE MEDICAL ASSOCIATION

Seventy-Sixth Annual Meeting, held in Kansas City,
 May 1, 2, 3 and 4, 1933

DR. JOSEPH W. LOVE, Springfield, in the Chair

The Role of Hepatic Function in Surgical Problems

DR. WARREN H. COLE, St. Louis: Adequate methods for determining impairment of hepatic function are still lacking. The multiplicity of functions of the liver is perhaps the greatest factor in the difficulty associated with the application of the various tests. After several years' experience with the dye test, utilizing the rate of excretion of phentetiothalein sodium following intravenous injection of 40 mg. per kilogram of body weight, I have been able to predict to a very helpful extent the relative operability of patients. I make no claims of superiority of phentetiothalein sodium over other dyes in estimating retention, if these dyes are given in doses much larger than the dose of from 3 to 5 mg. per kilogram of body weight, as is usually advocated.

The types of disease yielding most consistently high figures of retention of dye are confined largely to infections of the liver, associated frequently with gallbladder disease, and to diseases showing destruction of hepatic cells by toxic factors. During the early years of application of the test it was discovered that practically all the fatalities following cholecystectomy occurred in patients who showed a retention of dye above 50 per cent half an hour after injection (a retention of 10 per cent in half an hour is considered normal). I do not operate on patients with retention above 40 per cent (except emergencies) but postpone operation until bed rest, intravenous dextrose and transfusions have brought the retention down below this figure.

It was surprising to discover that the figures of retention might be only slightly elevated in patients with large livers such as produced by cirrhosis or even carcinoma (late stages excepted). Hepatic cells have an ability to regenerate very

rapidly. Since the injury to hepatic cells and displacement of these cells take place so slowly in diseases such as cirrhosis and carcinoma, it is logical to assume that regeneration is rapid enough to maintain the number of functioning cells near normal, except in the late stages of disease. There is perhaps no proof that the hepatic cells in cirrhosis or carcinoma (excepting the carcinoma cell itself) are injured until the disease becomes far advanced. This finding of retention only slightly above normal may indicate that the hepatic cells in the early stages of cirrhosis and carcinoma are not damaged but are merely displaced by the fibrous tissue or tumor growth, respectively.

Varicosities of the Broad Ligament

DR. ELLERY M. HETHERINGTON, Kansas City: Varicosities of the broad ligament produce marked symptoms. The arterial and venous anatomy of the pelvis explains why varicosities are so prone to form. The pathologic condition is due to passive congestion and includes cystic and fibrous changes in the ovaries, hyperplasia of the endometrium, cervical hypertrophy and fibrosis uteri. The etiologic factors are the anatomic peculiarity of the pelvic veins, general individual build, poor general health with low muscular tone, pregnancy, subinvolution, retroversion, prolapsus or descensus, pelvic tumors, obstipation, sexual overindulgence and increased intra-abdominal pressure. The chief symptoms are pelvic pain, which is dull and burning, most often left sided, worse on standing, partially or completely relieved by reclining, and increased on menstruation; sacral backache; changes in menstruation; bladder irritability, and reference of the pelvic pain down the inner thigh when standing. A corrective operation is offered whereby the uterus is suspended by plication of the round and broad ligaments. These ligaments are shortened, part of the veins ligated and the rest straightened by pulling them through or under a flap made in the anterior surface of the uterus. Anchoring is accomplished by four interrupted sutures on each side.

Narcolepsy

DR. E. T. GIBSON, Kansas City: The narcolepsy of Gelineau is characterized by two symptoms: (1) sudden imperative periods of sleep of short duration and (2) sudden transitory loss of power in part of or all the body with preservation of consciousness, preceded usually by a sharp emotional reaction, usually laughter or surprise. Recently reports from clinics in all parts of the world have shown that cases are becoming more frequent. I have studied six cases in the past year. Two pathologic conditions which bear some resemblance to narcolepsy are (1) cataplectic attacks, observed in a race of domestic goats from the Tennessee mountains, and (2) family periodic paralysis. Cases are reported which present unusual features of theoretical interest: (1) narcolepsy in two sisters, (2) a case in which the attacks were associated with myoclonic jerks, and (3) a case of cataplexy of several hours' duration. It is impossible to erect a consistent theory of narcolepsy at present. The only successful treatment for narcolepsy is ephedrine.

The Mechanism of Heart Block

DR. L. B. HARRISON, St. Louis: Heart block was defined by Mackenzie in 1906 as that condition in which the stimulus for contraction passing from auricle to ventricle by the muscular fibrils joining the auricle and ventricle is stopped or blocked on account of some deficit to those muscle fibers. The first to prove that the auricular impulse spread to the ventricle by passing over the muscular connection was Gaskell in 1883. It was demonstrated years ago that a delay may occur in the conduction of the cardiac impulse from the sinus node to the auricle in the human heart, so-called sinu-auricular block. If this block is not severe enough to produce dropped beats, it cannot be recognized either by clinical or by graphic means. As the block increases dropped beats appear, the beats following appearing in slightly less than multiplications of the normal beat intervals. Partial heart block includes all grades of block up to that condition in which no auricular impulses are transmitted to the ventricle. Mild cases of partial block or simple auriculoventricular delay are unrecognized except by graphic records. Occasional dropped beats and higher degrees of block are recognized clinically and sometimes accurately determined by observation of jugular pulsation and ventricular rate. Complete block gives the so-called idioventricular rhythm. The

mechanism may be explained by the failure of the auriculo-ventricular bundle to recover from previous activity, owing to faulty nutrition from disease, vagus nerve action, or fatigue, as in extreme tachycardia. The rate of the ventricles as a rule ranges between 28 and 40, while auricular rate may be normal or slightly increased. In bundle branch block the main or terminal branches of the bundle of His are blocked, giving all degrees of intraventricular block, the smaller branch blocks being unrecognizable, while blocking of either the right or the left bundle may be made out by means of electrocardiography.

Extrasystoles and Paroxysmal Tachycardia

DR. CARL R. FERRIS, Kansas City: Extrasystoles are the simplest and commonest abnormalities of cardiac rhythm. Paroxysmal tachycardia, related to extrasystoles in manner of production, is of more clinical significance. Premature beats (or extrasystoles) are of three types: auricular, ventricular and nodal, resulting from "ectopic" stimuli arising in the auricles, ventricles and auriculoventricular node, respectively. About one half of the persons in whom extrasystoles occur are unaware of their presence. Their chief clinical importance lies in the fact that resulting symptoms are frequently alarming and because they may be associated with otherwise unrecognized heart disease. The mechanism in the production of premature contractions is obscure. Their cause may be found either outside or inside the heart. Although relatively unimportant clinically, their presence justifies painstaking investigation into their etiology. The paroxysmal tachycardias are likewise auricular, ventricular and nodal in type. Paroxysmal auricular tachycardia is the most common and least important type. Conditions responsible for extrasystoles are responsible also for auricular paroxysmal tachycardia. Symptoms may be either mild or severe. The ventricular type is usually a serious disturbance of rhythm. It is found as a rule associated with serious heart disease. The prognostic significance of paroxysmal tachycardia of ventricular origin makes differential diagnosis important.

Treatment of the Cardiac Episodes of Middle Life

DR. O. P. J. FALK, St. Louis: In New York, where there was a continuous rise in cardiac deaths from 133 per hundred thousand in 1900 to 280 in 1928, 51 per cent of the cardiac deaths were between ages 40 and 70 and only 8 per cent under 40. The most frequent causes of heart disease after 40 are associated with vascular deterioration, such as coronary arteriosclerosis and the changes in the smaller arterioles so frequently associated with vascular hypertension. Aside from the fact that more people are being enabled to live to the age of cardiovascular degeneration, further contributing factors are the influence of heredity, the hypersthenic constitutional type and disorders of metabolism such as obesity and diabetes, together with the effect of the strain and speed of our highly competitive industrial civilization, in which the art of quiet relaxation seems to have been almost entirely overlooked. Two developments of outstanding importance in present-day cardiology are the importance of analyzing the early subjective expression of organic heart disease and the recognition of certain reliable objective criteria of organic heart disease.

Gastric and Duodenal Ulcer

DRS. J. W. THOMPSON and HORACE W. SOPER, St. Louis: Experimental surgery has not provided conclusive proof concerning the etiology of gastric and duodenal ulcer, and the practical points of the management have always been subject to wide variations. Recent years have led to some exact differentiation between cases requiring medical or combined surgical and medical attention. The roentgen ray is the chief reliance in diagnosing these conditions. Duodenal ulcers practically never undergo malignant degeneration. Medical treatment in the Soper-Mills Clinic is reserved for early uncomplicated duodenal ulcer. The benign gastric ulcers yield readily to dietetic and hygienic management, particularly with the employment of the Levin indwelling nasal catheter, which is permitted to advance into the duodenum or jejunum. This procedure amounts to practically the same as a surgical jejunosotomy and is as effective as healing even large benign gastric ulcers. The ulcers not responding to the so-called therapeutic test of healing should be subject to surgical treatment. Several

types of complicated duodenal ulcers are amenable only to surgical measures. Among these classifications may be mentioned the acute perforated, recurrent hemorrhagic, chronic recurrent, organic obstructive, multiple ulcerative and chronic perforating types. The type of operation to perform in the surgical treatment of duodenal ulcer varies with the anatomic and pathologic characteristics discovered in each individual instance. Gastro-enterostomy is by far the operation of choice in the majority of instances. Pyloroplasty and gastric resection or gastroduodenostomy are other types of procedure applicable to the treatment of duodenal ulcer in the chronic form. In the acute perforated ulcer, conservative closure of the perforation without gastro-enterostomy seems to be the procedure of choice. The postoperative management is important. The mechanical procedures of surgery cannot be expected to permit unphysiologic abuses of the patient's stomach by indiscretions in dietary and hygienic habits. The elimination of foci of infection is also considered important.

Renal Complications of Gallstone Disease

DR. WILLARD BARTLETT, JR., St. Louis: Eight cases of acute nephritis and a questionable ninth case of renal insufficiency and suppression of urine complicating gallstone disease are reported. I have renal function tests done as a routine procedure in all cases of biliary tract infection. Tests of function employed are phenolsulphonphthalein excretion, determination of blood nonprotein nitrogen, and urine concentration tests. I believe that the nephritis occurs primarily as a result of the action on the kidney parenchyma of toxins from the infecting organism. Jaundice may be a contributing factor but is not constant. Attempts to reproduce the clinical picture in animals have invariably failed. This series of cases formed an incidence of more than 10 per cent of all patients with gallstone disease over the period studied. The complication is very serious. The majority of patients in other series have died, the complication having occurred after radical operation. This is avoidable by routine preoperative estimation of renal function. When function is impaired, the operation should be divided into stages, preliminary cholecystostomy under local anesthesia only being done at the first hospitalization, with maintenance of biliary drainage by a Pezzer catheter for from three to six months. In this series, the complication occurred preoperatively in one patient before its significance was recognized and recurred after cholecostomy, with death. In the remaining eight cases it was present on admission or developed shortly after; three of these patients died without operation, three recovered after cholecystostomy and two died on the second and eleventh days, respectively, one of pulmonary embolus and the other of pneumonia. Urinary function was recovered in both.

Mycotic Infections of the Skin

DR. THOMAS B. HALL, Kansas City: Mycotic skin infections may be divided into three groups: The first group includes all superficial dermatoses due to fungi other than *Monilia*; these number fourteen. In the second group are eight superficial dermatoses due to *Monilia*. The third group includes six mycotic skin diseases which are characterized by deep invasion of the skin by fungi. The *Monilia* infections seem to require usually a pathologic terrain and are frequently found in diabetic patients, hyperbese persons with overlapping skin folds, and those who work in special industries and keep their hands immersed in water for prolonged periods. Fungous infections of the hands and feet are the most prevalent of all skin diseases and are grouped into the following types: macerative interdigital, vesiculobullous, exfoliative, hyperkeratotic, moniliasis and mixed (epidermophyton and *Monilia*). Combinations of these types are common. The complications of mycotic infections of the hands and feet are classified into two groups. There are those which develop from injury to the skin by the fungi, producing a condition favorable to the invasion of other organisms. In this manner pyoderma, lymphangitis, phlebitis, lymphadenitis, recurrent erysipeloid attacks and septicemia may occur. The second group includes the "id" eruptions, which are due to the fungi themselves provoking skin lesions remote from the primary focus. Vesicular, bullous, papular and urticarial lesions, as well as erythema multiforme, erythema nodosum and generalized exfoliative dermatitis have been described as occurring from fungous infections of the feet

and hands. Prolonged irritating topical treatment to acutely inflamed cases seems to favor the development of the "id" eruptions. Treatment should be individualized and based on clinical manifestations. All vesicular, secondarily infected and acutely inflamed cases should be brought well under control by soaks and lotions before ointments are applied. The generalized "id" eruptions require sedative treatment.

Anorectal Infection: Its Relation to General Medicine

DR. F. B. CAMPBELL, Kansas City: Anorectal diseases may be classified as those due to (1) structural weakness (hemorrhoids, prolapse, and so on), (2) infections and (3) injury. The majority of anorectal infections are secondary to infections of the respiratory tract or the mouth. A few are caused by acute or chronic infections of the intestinal tract and a few from a normal intestinal flora, from enema tips and from rough paper. The rectum is predisposed to trauma by its funnel-like shape, by a tendency to spasm of the sphincters, by encroachment on its lumen by varicosities, and by trauma from constipation. Functionally, it is predisposed to infection by an acute diarrhea and by liquid stools from laxative or soap suds enemas, which remove the normal protecting mucus, leaving the mucosa open to chemical irritation and infection. The crypts are the most vulnerable point and cryptitis the most common lesion, and it may become chronic. Hemorrhoids may result from or be a predisposing cause of infection. It should be remembered that there is a close relationship between anorectal disease and gastro-intestinal symptoms, nervousness, headache, backache or leg pains. Malfunction or disease of the colon may hinge on anorectal disease. Treating a spastic colon while ignoring anorectal disease is illogical. Best results require cooperation between the proctologist and the internist.

Transurethral Prostatectomy: Indications and Limitations

DR. J. HOY SANFORD, St. Louis: Some able men prefer transurethral surgery to prostatectomy for the reason that the end-results are as good, the procedure is much safer and is attended with reduced mortality, there is less systemic and local reaction, and much less hospitalization is required. Other equally able men recommend transurethral surgery in selected cases as a substitute for prostatectomy but deny its usefulness in the larger obstructions for the following principal reasons: Sufficient gland cannot be successfully removed in single or multiple resections to give the desired end-results. There is a possibility of recurrence. There is danger of sepsis and hemorrhage. Certain parts of the gland are obscure to this type of attack. There is danger of infection in a closed bladder without adequate drainage (this applies only to large obstructions necessitating extensive electrocoagulation. It is a major surgical procedure requiring unusual skill and yet without sufficient supportive evidence to be accepted by the majority. I am convinced that from 75 to 100 cases should be done before any one classifies himself as capable.

Avoiding Complications in Gynecologic Radium Therapy

DR. KIP ROBINSON, Kansas City: Radium is the treatment par excellence of various malignant and benign gynecologic conditions, particularly carcinoma of the cervix. Infection plays a prominent rôle in cervical carcinoma. Pyometra may result from damming back infected material during treatment, and it may be necessary to introduce a small drainage tube alongside the radium capsules. Healing stenosis of the cervical os may produce a late pyometra, and dilatation and drainage must be done. Growths along the vaginal wall are treated with surface applications to produce as much shrinkage as possible before interstitial implantation is used. Much antiseptic douching is employed because of danger of setting up a pelvic cellulitis by puncturing through potentially infected areas. Great caution is used when dilating a carcinomatous cervix to avoid spreading the growth or producing infection. Cauterization should not be too deep followed by intensive irradiation because of the danger of extensive slough formation. With proper shielding and filtering, growths along the vaginal walls are treated without danger of rectovaginal or vesicovaginal fistulas, and even in extremely advanced cases

good palliation is obtained. A latent pyosalpinx may be stirred up by irradiation and should be removed surgically before treatment. Fibroids that are too large, are too rapidly growing, are associated with pressure symptoms, are pedunculated, are degenerated, are associated with other intra-abdominal lesions requiring surgery or are present in very young or very anemic sick patients should not be treated with radium but by surgery. Menorrhagia and metrorrhagia in young girls are treated only by very small doses to preserve fertility. Radium therapy, wisely administered, carries a much lower mortality in treating certain malignant and benign gynecologic conditions than surgery and is more effective.

Tuberculosis in Childhood

DR. SAM H. SNIDER, Kansas City: Pulmonary tuberculosis is not common in children; the disease is a tuberculosis of the lymphatics following the primary inflammatory manifestation. Symptoms are inconspicuous, the only common ones being fever and malnutrition. There usually are no abnormal physical conditions in the chest of a tuberculous child. Diagnosis rests on a positive tuberculin test (Mantoux or Pirquet). The extent of the involvement is shown by the roentgen ray, which, if used very early, may show the primary (Ghon) tubercle or inflammatory involvement in the parenchyma. When the infection becomes manifest, however, this Ghon tubercle has usually calcified or resolved and only a shadow of a calcified tubercle (Ghon nodule) remains, or resolution may be complete, leaving no scar. The roentgen rays usually show only hilus thickening and calcification and increased peribronchial markings. Pneumonic changes are rare. The immediate prognosis is good; sometimes a progressive tuberculosis develops immediately. Usually there is a long interval between infection and the true pulmonary (adult type) tuberculosis. The campaign against tuberculosis is to prevent infection of children, and this involves education of the public to the danger of kissing and indiscriminate handling of young children by tuberculous adults. Children are seldom a source of infection because they seldom expectorate tubercle bacilli. The adult with the open cavity is the greatest menace.

Diagnosis and Prognosis of Adult Pulmonary Tuberculosis

DR. G. D. KETTELKAMP, Koch: The history as to exposure to tuberculosis is of extreme importance. Since all pulmonary tuberculosis has a stage at which the tubercle bacilli are not liberated into the sputum, failure to find tubercle bacilli is of little value; if the lesion is such that one should expect a positive sputum, a negative sputum should put one on guard for a nontuberculous infection. The differential blood count is a great aid in measuring activity in pulmonary tuberculosis. The Arneith and Schilling shift to the left of the neutrophils as well as the relative percentage of lymphocytes, neutrophils and monocytes must be considered in interpreting the differential blood count.

Nonsurgical Treatment of Pulmonary Tuberculosis

DR. J. B. STOKES, Mount Vernon: The general medical profession should be more interested in the nonsurgical treatment of pulmonary tuberculosis, particularly artificial pneumothorax. In each community there should be a physician adequately trained to continue pneumothorax treatments. The most common complication of artificial pneumothorax is pleural effusion. In significant amounts it was present in only 23 per cent of our series at the Missouri State Sanatorium. The most common causes of pleural effusions are irritation of the air and the tearing of adhesions. Uniform pressures tend to reduce the incidence of effusions. Less common complications of artificial pneumothorax are pleural shock, air embolism, spontaneous pneumothorax and subcutaneous emphysema. The greatest hindrances to a successful artificial pneumothorax are pleural adhesions. How much they interfere depends on their extent, type and location. Artificial pneumothorax should be continued, in general, two or three years, and reexpansion preceded by phrenic neurectomy. Supervision at that stage is very important. Ordinarily, artificial pneumothorax cannot be reestablished. This is particularly true after effusions. At the Missouri State Sanatorium, artificial pneumothorax was reestablished after two months and later followed by oleothorax.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk () are abstracted below.

Pneumonia in Kerosene Poisoning.—Waring reports nine cases of kerosene poisoning in children with pulmonary complications. Leukocytosis with an increased polymorphonuclear percentage has been characteristic. The blood cholesterol appeared to be reduced, but no other chemical change was noted. Animal experiments tended to confirm the clinical opinion that the serious cases of kerosene poisoning are due to the aspiration of kerosene into the lungs, with production of inflammation and edema, and a potentially fatal pneumonitis. Supportive measures, especially stimulation with caffeine, have been used. Colonic irrigations and gastric lavage have been given, but, if regurgitation is to be avoided, the use of lavage might be questioned. In two of the patients who recovered, postural drainage was instituted but no direct evidence of its efficacy was noted. The blood chemical studies have not indicated any line of treatment. Because some of the children showed acetone in the urine, dextrose has been given to the patients seen recently.

Diagnosis of Jaundice.—Flood and his associates reviewed the records of 235 cases of nonhemolytic jaundice in order to determine what clinical evidence may be of assistance in differential diagnosis. It is not practicable to differentiate clinically early in the disease between cases with catarrhal jaundice and cases which are to develop acute yellow atrophy, as the early clinical pictures in these conditions seem to be identical. The symptoms and signs in necrosis of the liver due to some drug, such as arsphenamine or cinchophen, are the same as those seen in catarrhal jaundice or acute yellow atrophy, with the exception that patients with the latter conditions may give a history of antecedent infection of the upper respiratory tract. When the history of the exhibition of such a drug can be obtained, the diagnosis of liver necrosis is facilitated. Of particular assistance in the diagnosis of catarrhal jaundice in the middle aged is the short duration of the jaundice at the time when the patient feels sick enough to present himself for examination, and the usual vagueness of the presenting symptoms: a moderate degree of dull epigastric pain, malaise, anorexia and nausea or vomiting. Tenderness over the liver is present in more than 50 per cent of the cases. Minor signs that may be

of assistance are the "amine breath" and an acneform eruption. A high serum bilirubin favors the diagnosis of catarrhal jaundice or acute yellow atrophy rather than carcinoma or calculus. Calculus in the common bile duct offers few difficulties in diagnosis when there is a history of one or more attacks of the characteristic pain with local tenderness and leukocytosis. In carcinoma of the pancreas with jaundice, pain is the common initial symptom and is present early in the disease in the majority of cases. This pain is usually dull, boring and epigastric in location. In carcinoma of the bile duct or gall-bladder the clinical picture is usually not different from that seen in carcinoma of the pancreas. It is dangerous to hazard an opinion as to the exact location of a neoplasm obstructing the biliary tract. Primary carcinoma of the liver should be suspected in a patient who shows evidence of cirrhosis of the liver, who gives a history suggestive of some type of neoplasm and who has fever, upper abdominal pain and jaundice of slight degree.

Erythrocytes in Pellagra.—Using the most accurate available methods, Turner made erythrocyte counts, determinations of hemoglobin and percentages of packed red cells for seventy samples of blood from fifty patients with typical pellagra. The results with the calculated mean corpuscular volume, mean corpuscular hemoglobin, corpuscular hemoglobin concentration, volume index, color index and saturation index along with certain clinical features are reported. Of the pellagral patients, 56 per cent showed no appreciable anemia, 16 per cent showed slight or questionable anemia, 12 per cent showed moderate anemia and 12 per cent a severe anemia, while 4 per cent showed an extremely severe anemia. Two thirds of the patients who died showed no anemia according to the methods and standards used. Among those with severe anemia, other diseases that might have caused anemia were common. Patients who suffered from diarrhea did not appear to be more anemic than those without diarrhea. The author discusses the influence of dehydration in observing anemia. Anemia, when present, was definitely of the chlorotic, normocytic or microcytic type and in no instance of the macrocytic type. Thirty-four per cent of the patients had erythrocytes with corpuscular hemoglobin concentration less than normal, while in 66 per cent the concentration was within the normal range. The average size of the red cells tended to diminish in proportion to the severity of the anemia, contrasting with the opposite rule for pernicious anemia. The blood picture in the differential diagnosis between pellagra and pernicious anemia or sprue is of importance.

Bundle-Branch Block.—Graybiel and Sprague present an analysis of 395 cases of bundle-branch block. The diagnosis of bundle-branch block can be made with certainty only by the use of the electrocardiograph. From the standpoint of diagnosis and prognosis it is important to determine its presence in cardiac patients. Bundle-branch block almost invariably indicates serious organic disease of the heart, usually coronary disease; the average duration of life in the 223 fatal cases in the authors' series after the discovery of the conduction fault was one year and two months, but eighty-five other patients are still alive after an average of two years and eleven months following the discovery of the bundle-branch block. Partial bundle-branch block must be regarded clinically as equally significant with complete bundle-branch block, the prognosis in the two being essentially the same.

Circulation in Lower Extremities.—Kramer studied the circulation in the lower extremities of 150 patients, most of whom presented a history of diabetes. The merits and failures of the various methods that he used for his study appear to be as follows: The oscillometer measures the degree of pulsation of the vessels in a particular area without personal equation as an arbitrary factor in determining results. It gives information about the deeper vessels which cannot be palpated. It may suggest the existence of collateral circulation when definite lesions of the vessels are apparent. The reaction of the capillaries to histamine indicates the condition of the superficial circulation and indirectly of the deeper vessels. It may be employed as a guide to the capillary circulation and nutrition of the tissues. Physical examination of the extremities may throw some light on the status of the circulation if one ascertains the dorsalis pedis pulse, palpates for sclerosis as well, notes the warmth or coldness of the feet, and searches for various types

of lesions and the condition of the veins. Roentgen studies in 111 patients of the 150 showed evidences of calcification in fifty-one out of the sixty-three patients who presented evidences of a deficient circulation (81 per cent), while in the remaining twelve (19 per cent) the observations were negative. Of forty-eight patients with presumably efficient circulation, thirty-nine were negative and nine showed calcific deposits in the vessels. The author concludes that information derived from the various tests may be helpful to the surgeon when the question arises as to the advisability of operation for the relief of arterial spasm; in differential diagnosis of vascular disease, and in early diagnosis of impaired circulation. When amputation has been decided on, in some selected cases, the site for operation may be determined by the results of the studies.

Pyemia.—Rubin points out that pyemia following acute tonsillar infections occurs in from 1 to 2 per cent of such cases. Chills occurring from two to three days after the beginning of a sore throat, or one occurring a week or two after an angina that has subsided, with a swelling along the anterior part of the sternocleidomastoid muscle or over the parotid region, may be the beginning of pyemia. One must exclude pneumonia, pyelitis or one of the blood dyscrasias, such as agranulocytosis or leukemia. Once the diagnosis is established, immediate exploration of the neck is advisable. When the cavernous sinus is involved, the infection spreads by way of the pterygoid plexus or the petrosal sinuses. It has been demonstrated that thrombi are present in the tonsillar veins in nearly all cases of acute tonsillar or peritonsillar inflammation. It is possible that, in some cases, abscesses of the lungs occurring after tonsillectomy may be explained on the basis that a tonsillectomy is done before the inflammation of the tonsil has subsided. The trauma resulting from the operation causes the phlebotic process to spread. In many cases the inflammation in the tonsil may not be demonstrable. The anaerobic streptococcus is the organism most frequently found. Blood cultures are positive in about 50 per cent of the cases. The presence of anaerobic streptococci or bacilli in the blood stream should make one consider the possibility of a preexisting tonsillar infection as the cause. In two of the author's four cases, which he reports, the blood culture was positive. The prognosis appears to be more grave when such organisms are present. Claus suggests an exposure of the structures of the neck from the mastoid process down to the clavicle. The parapharyngeal space should be exposed, and any infection found should be dealt with. Ligation or resection of the jugular and facial veins is also carried out. If it is impossible to determine on which side the infection is taking place, he suggests exposing the neck on both sides, and if the jugular vein is involved on one side, he suggests ligating or resecting it and ligating and resecting the facial vein on the opposite side. Waldapfel opens the parapharyngeal space and evacuates the abscess, at the same time protecting the mediastinum. Kissling obtains good results by simply opening the parapharyngeal space and draining the abscess. He ligates the jugular vein above and below the facial vein and opens the latter. In some cases the thrombus may extend to the jugular bulb or even upward, so that it may become necessary to open the mastoid process to remove the sinus plate and expose the lateral sinus. Meningitis may be caused by involvement of the jugular bulb and the lateral sinus in this condition. In every case of sepsis

following angina, the parapharyngeal space should be explored. There is a difference of opinion as to whether the tonsils should be removed at the time of operation.

Vidian Neuralgia.—Vail states that anatomic studies show the close relation between the great superficial petrosal nerve and any pneumatic cells which may be present in the anterior portion of the petrous bone. It has also been shown that impulses coming over the great superficial petrosal nerve can reach the orbit and from there pass over the terminal branches of the ophthalmic division of the trigeminus by means of the anastomosis between these nerves and the orbital branches of the sphenopalatine ganglion. He reports three cases of vidian neuralgia to show that irritation of the vidian nerve in the floor of the sphenoid sinus causes ocular and orbital pain. The ocular and orbital pains described by patients with suppuration of the petrous bone show a great similarity to those found in cases of vidian neuralgia. The great superficial petrosal nerve is extradural throughout its course. The gasserian ganglion and its division are above the dura. Hence there must be a dural involvement before the gasserian ganglion and its branches are affected.

Otitis Media in Scarlet Fever.—Williams observed that the incidence of otitis media in a series of 14,733 patients with scarlet fever was 10.8 per cent. In about one third, the disease was bilateral. The incidence of mastoiditis requiring surgical treatment was 1.1 per cent. The mortality in a series of 1,335 patients suffering from scarlet fever with acute suppurative otitis media was 4 per cent. The mortality in a series of 167 patients with scarlet fever on whom mastoidectomy was performed was 10.8 per cent. Early incision of a bulging tympanic membrane and incision of a ruptured tympanic membrane when the rupture is inadequate for proper drainage tend to lower the incidence of acute mastoiditis requiring surgical intervention in scarlatinal otitis. Repeated incision of a tympanic membrane is seldom of value. Of the 1,335 patients with acute suppurative scarlatinal otitis media, ninety-one, or 0.5 per cent, were children under the age of 10. The peculiarity of the eustachian tube in the child and the concurrence of pharyngeal and faucial tonsils and paranasal sinusitis predispose to the development of acute and chronic aural complications. In scarlet fever, aural complications of any degree of severity may arise at any time, from the first day of the acute symptoms to the last day of convalescence. The incidence of tonsillectomy and adenoidectomy in the 14,733 patients with scarlet fever was 6.8 per cent. In otitis media of scarlet fever there is no great tendency for the disease to extend from the bone to the meninges, as shown by a total of seven patients with meningitis from the series of 14,733 patients. Not infrequently the infection passes through the middle ear and appears as a postauricular edema, redness or a subperiosteal abscess, leaving the tympanic membrane intact. The useful principles of treatment available today are essentially those that were available twenty years ago.

Bismuth in Neurosyphilis.—Mehrtens and Pouppirt believe that ultimately some form of bismuth therapy will become suitable for neurosyphilitic disease because of its effectiveness in general syphilis. They recognize that bismuth does not penetrate into the central nervous system, and, while they are unprepared to state that clinical improvement and ability to penetrate into the central nervous system run parallel courses, it seems

to them almost necessary that a drug penetrate the central nervous system in order to produce therapeutic results. In the treatment of neurosyphilis, each case, by the very nature of its pathology, necessitates long drawn out therapy. It is imperative that the drugs used be such that their prolonged use shall not damage the kidneys or other vital organs. In a carefully observed series of cases treated intensively with bismuth compounds over a period of many months and years, no evidence of nephritis was elicited. This, of course, is quite contrary to the usual experience with preparations of mercury and arsenic. Their clinical experience with iodobismuthol containing bismuth as an anion indicates that its therapeutic effectiveness parallels its ability to penetrate into the meninges. The possibility suggests itself that the clinical usefulness of any bismuth preparation in the treatment of neurosyphilis is dependent on its ability to assume an electronegative form.

Coronary Disease.—From a review of the etiologic factors presented in the records of coronary occlusion in 8,500 necropsies, Evans and his associates conclude that: 1. The majority are caused by coronary artery atherosclerosis and resultant thrombosis. 2. Much less frequently do embolism and syphilitic arteritis play a part. In about 10 per cent of cases of syphilitic aortitis, narrowing of one or both coronary orifices results; but rarely, if ever, does the lesion extend far beyond these orifices. 3. Rarely, as in some instances in childhood, do inflammatory changes without arteriosclerosis serve as a focus for thrombosis. 4. Arterial hypertension with resultant cardiac hypertrophy characterizes a large proportion of these cases. 5. The average age at death is 62 or 63 years. 6. There is a remarkable preponderance of men over women who succumb to this disease; in this series, three and two-tenths men to one woman. 7. The condition is frequently associated with diabetes, but coronary patients with diabetes do not die earlier than those without diabetes. 8. No etiologic relationship could be determined with infectious diseases or foci of infection, or with the use of alcohol or tobacco.

Carcinoma of Tongue.—Beck and Guttman state that malignant epithelial growths of the tongue vary in their histologic structure, biologic course and response to irradiation. Adult, fully differentiated carcinomas are best treated by endothermic excision, if small and localized in the anterior portion of the tongue. Anaplastic, embryonic, undifferentiated growths are best treated with radiation, preferably the 4 Gm. bomb and in association with interstitial radium or radon, if necessary. The gland-bearing area of the neck must receive appropriate

attention in every case. When no palpable glands are present in the neck, prophylactic irradiation is necessary, preferably with a 4 Gm. pack. Palpable glands, secondary to a fully differentiated primary growth in the tongue, are best treated by a radical gland resection in conjunction with radiation. Palpable glands, secondary to an anaplastic undifferentiated primary growth, are treated with radiation alone, and surgery on the neck is contraindicated.

Relief of Pain in Diseases of Feet.—Perlow believes that relief of pain is a major problem in the treatment of peripheral circulatory disturbances of the lower extremities. To relieve the pain in such cases, the painful area must be accurately outlined and the nerves that supply it with cutaneous fibers injected with alcohol. To attempt to inject the nerve with alcohol through the skin is dangerous, because sloughing of the tissues will result. It is safer to isolate the nerve through a small incision. Under local anesthesia with a 1 per cent solution of procaine hydrochloride the desired nerve is isolated above the ankle, and from 0.5 to 2 cc. of a 95 per cent alcohol solution is injected directly into the trunk. The nerve is then dropped back into place and the wound closed with fine catgut or silk. The surrounding tissues should be protected from the alcohol. Because of the poor healing power of the tissues with which one is dealing, it is essential to isolate the nerve trunk high up above the ankle and to work through as small an incision (1 by 1½ inches) and with as little injury to the tissues as possible. This requires a detailed knowledge of the course of the various nerves and their relations to the surrounding tissues, especially the adjacent blood vessels, as injury to the already inflamed artery may easily swing the course of events from cure to gangrene.

Treatment of Dementia Paralytica.—Hoverson and his associates gave, over a period of three years, 124 male patients suffering from dementia paralytica a total of 4,198 injections of typhoid vaccine. Arsenicals and mercurials followed. All the patients received an initial injection of 50 million killed typhoid bacilli. Subsequent doses were always increased, even when no satisfactory temperature response was obtained. Dosages as high as 27 billion killed typhoid bacilli were given. Of the 124 patients 30 died, 6 escaped, 43 improved, the progress of the disease was checked in 16, 6 deteriorated, the treatment was discontinued in 9, and 14 were discharged. Of the 14 patients who improved sufficiently to be discharged, 11 are now self supporting. The authors also treated 32 dementia paralytica patients by hyperpyrexia, using an electrical cabinet, especially constructed for them, to furnish the source of external heat. They conclude that the electrical cabinet offers a safe and efficient means of maintaining hyperpyrexia. There is a close correlation between the number of hours a high temperature is maintained and the clinical results obtained. The treatment is carried out without subjecting the patient to any really high external heat. The highest temperature recorded in the cabinet itself was 126 F. In the course of the usual treatment the temperature of the air about the patient ranges from 120 to 126 F.

Measles Convalescent Serum.—Levinson and his associates treated 287 measles contacts with measles convalescent serum, obtaining complete protection in 60 per cent and attenuation of the disease in 33 per cent. The minimum dose employed should not be less than 5 cc. The age, weight, general physical condition, presence of some other infection, nature of contact, length of contact, and interval elapsing between initial contact and injection should be considered in determining the necessary amount of serum to make an adequate dose. Every case should be individualized and, depending on the factors influencing the efficacy of the serum, the proper dose and optimal time of administration should be decided to produce the desired result for each case. It is preferable to allow the development of sero-attenuated measles, with its resultant active immunity, except in sick or poorly nourished patients. In these patients, complete protection should be attempted under these adverse conditions, and at some future and more favorable time, on reexposure of the child, the usual plan of sero-attenuation can be followed. Serum from patients who have had measles within two or three months seems to be just as protective as that from recent convalescents. Twenty-five measles contacts received adult pooled normal serum with complete protection in 56 per

cent and sero-attenuation in 40 per cent. Pooled normal adult serum in amounts of from 20 to 40 cc. makes an effective substitute for convalescent serum and can be used with confidence.

Treatment of Hydronephrosis.—According to Walters, in the presence of a renal parenchyma the function of which is sufficiently normal, complete removal of the obstructing factors producing the hydronephrosis should give relief of the obstructive symptoms, and the pelvis and calices should return to within reasonably normal limits of size. In his experience, resection of the hydronephrotic renal pelvis gives excellent results in treatment of hydronephrosis in properly selected cases: complete relief of obstructive symptoms followed bilateral resection of the renal pelvis with reduction of the pelvis and calices to within normal limits of size in two of his patients. Ureteropyeloneostomy has relieved, over a period of almost four years, hydronephrosis in a solitary kidney, in which obstruction was complete at the time of the operation. If one should choose to reimplant the ureter into the dependent part of the renal pelvis, accurate anastomosis should be made between the cut end of the ureter and the opening made in the pelvis, for any redundant portion of the ureter extending into the pelvis may serve as an obstructing valve. Conservative procedures, such as resection of the renal pelvis, reimplantation of the ureter, or removal of such obstructions as peripelvic tissue, are most strikingly indicated when the hydronephrosis is bilateral, or, if it is unilateral, when sufficient renal parenchyma remains to justify its preservation. The necessity for conservative procedures for relief of the obstruction when the kidney is solitary is apparent. The best procedure is the one that produces adequate and complete relief of the obstruction, with minimal disturbance of the renal pelvis or ureteral tissues.

Study of Ureteral Calculi.—Ravich states that, of all the etiologic theories which had been advanced, urinary stasis seems to be the only constant factor necessary for a stone to form in the urinary passages. The chemical character of the stone seems to depend on the pH of the urine, which may change from time to time and accounts for the different laminae so often demonstrated in stones. Calculi seem to form when, as a result of urinary stagnation, some change occurs in the secretory function of the tubular epithelium causing coalescence or diminution of the protective colloids and consequent precipitation of the unattached crystalloids. Trauma, faulty diet, infection and foreign bodies are often contributory causative factors in the presence of stasis. The 2:1 ratio of ureteral calculi in males and the 80 per cent incidence in adults of from 21 to 50 years of age correspond with the greatest incidence of inflammatory conditions of the adnexa in males and females. This is borne out by the fact that of the 393 prostatic examinations recorded only 82, or 21 per cent, showed what appeared to be normal prostates and seminal vesicles, the remainder showing some degree of recognizable pathologic condition. The passage of ureteral stones is hindered by physiologic narrowings, kinks, strictures, fixation of the ureter and atony of the ureteral musculature. Of the 758 private cases of ureteral calculi that the author treated during the past ten years, about 69.8 per cent were in men and 30.2 per cent in women. The roentgenogram was positive in approximately 90 per cent, and most of the remainder were diagnosed by the wax tip catheter, which is an important diagnostic measure. Approximately 83.6 per cent of the patients required cystoscopic manipulation, 6.3 per cent passed their calculi spontaneously, and 11.2 per cent were operated on without a single mortality. Recurrence was noted in 3.4 per cent, chiefly in those patients who refused follow-up treatment by ureteral dilation.

Spinal and Inhalation Anesthetics.—Smith gives the values of spinal anesthesia as follows: 1. There is no irritation to bronchial and pulmonary mucous membranes, and consequently fewer pulmonary complications. 2. Complete muscular relaxation is obtained, requiring less manipulation of viscera. 3. There is less postoperative nausea and there are fewer gas pains. 4. There is less dehydration, as fluids may be given during and immediately after operation. 5. There is a maintenance of cooperation between the patient and the surgeon. 6. It probably offers a safer anesthesia in cases of hypertensive heart disease. 7. Patients are grateful, especially if they have previously had disagreeable after-effects from inhalant anesthetics. The dangers of spinal anesthesia are in: (1) operations above the diaphragm, (2) extremely low blood pressure, (3) brain and spinal cord disorders, (4) skin infections about the site of spinal puncture, and (5) the psychic attitude of patients who object to being conscious while the operation is in progress. The value of inhalation anesthesia lies in operations above the diaphragm, in unconsciousness for the patients who demand it, and in cases of extremely low blood pressure. Its dangers are possible pulmonary complications, changes in blood chemistry with toxicity, metabolic disturbances and dehydration. There are advantages and disadvantages for both types of anesthesia. The selection of either type should be made with due delibera-

tion, and when there is no particular choice to be made the decision should be left with the patient.

Treatment of General Infections.—Hume believes that generalized infection, blood poisoning, blood stream infection, septicemia and septicopyemia designate one of the most dreaded conditions. Early supportive treatment to raise resistance—even transfusions of blood in certain cases with threatening localized infection, weakness and anemia—are apt to be more effective before than after blood stream invasion. Once blood stream infection sets in, treatment should consist of surgery to eradicate sources of infection, if such sources can be found, and if they lend themselves to surgical treatment; supportive treatment such as rest, proper care, proper food, liquids, elimination and transfusions of blood; the use of antiseptics intravenously, and anti-serums and vaccines. Blood transfusion in septicemias, except in occasional cases, has been rather disappointing, but the author regards it as ranking next to surgery in importance in the treatment and as the chief means of supporting the patient. He uses it regularly and sometimes repeatedly. He concludes that, in the unfavorable reactions occurring after transfusions, incompatibility is most to be feared, and unfailing care should be exercised in grouping and cross-matching bloods; also more care should be exercised in the selection, examination and preparation of donors.

Physiology and Some Diseases of Respiratory Mechanism.—According to McCormack, departures from the normal physiologic balance should be treated to correct that balance. The control of the administration of gases is accurate and a response of the tissues is immediate. The knowledge of the chemical equations, of normal existence when compared with the departure from normal in pathologic conditions, dictates the character and amount of gases to be supplied. Nature knows few irreversible equations. Oxygen should not be used alone to correct these pathologic physiologic conditions. Carbon dioxide and oxygen are always present in their normally varying proportions in the tissues and are dependent on each other, during normal life; therefore, also in pathologic conditions. Carbon dioxide and oxygen, administered correctly and early, will reduce the present fetal mortality. Early proper carbon dioxide and oxygen therapy will reduce the mortality in pneumonia as well as shorten the duration of the illness and lessen the incidence of complications. Carbon dioxide and oxygen mixtures must be varied in each case and at different times in each case; therefore, ready-made mixtures are inadequate when the skilled physician is in charge.

Essential Uterine Bleeding.—Kretschmar examined the records of seventy patients all under the age of 25. The patients entered the hospital with a chief complaint of excessive bleeding and in no instance was there any gross evidence of pathologic changes in the pelvic organs. These cases are usually diagnosed as essential uterine bleeding or idiopathic uterine bleeding. A fairly large proportion of the patients of this type (86 per cent in the author's series) present a basal metabolic rate below zero but frequently within the generally considered lower limit of normal, or minus 16 per cent. Most of these patients also have a glandular hyperplasia of the endometrium (80 per cent). The careful use of thyroid extract in doses sufficient to raise the

basal metabolic rate above zero and to maintain it is beneficial in a large proportion of cases (73.9 per cent). Curettage is of limited therapeutic value and is seldom indicated, except when it seems advisable to rule out malignant disease of the uterus. The roentgen rays, radium and hysterectomy are effective in the treatment of this condition but should be used only as a last resort in young women. The author states that evidence from his series and other recent contributions indicates that basal metabolic rate determinations within the generally considered low limit of normal minus 16 per cent may be definite evidence of mild hypothyroid states which can be benefited by the careful administration of thyroid extract. If this is true, the limit of normal for minus rates should be changed.

Undulant Fever in Children.—Sander reports six cases of undulant fever in children aged from 17 months to 11 years. He believes that the incidence of Brucella (Alcaligenes) infection is much more common in children than is suspected; also that a great many of these cases are being persistently misdiagnosed as influenza or "intestinal flu," summer complaint, rheumatic fever, malaria, tuberculosis, adenoid and tonsil infection, gastroenteritis, worms, teething, and "what not." He urges that children, presenting a clinical syndrome similar to any of the mentioned complaints, and in whom these other common diseases can be positively ruled out, be given the nucleoprotein skin test and that their blood be tested for phagocytic activity against Brucella abortus. If their blood cells show a lack of phagocytic activity, he believes that the children should be given intramuscular injections of brucellin until their cells show high phagocytic activity for Brucella in vitro. An agglutination test should be done with Brucella abortus in every case, but if the test is negative, it does not necessarily follow that the patient does not have undulant fever. Other tests are necessary to eliminate this disease, the intradermal and opsonocytaphag test.

Cardiac Neurosis.—Richardson states that cardiac neurosis is the persistent fear of premature death or invalidism through the medium of heart disease. The latent potentialities for this or other neuroses are present in all of us but need the right set of circumstances and events for development. Persons with unstable nervous systems and poor endowments from parents are rendered more susceptible. Any circumstance that sufficiently excites fear in relation to the heart may be the starting point of a cardiac neurosis. This basic fear may be aggravated by improper handling by physicians. A diagnosis of cardiac neurosis should be made only after the complete history, physical examination, and graphic records (if available) have ruled out all other possibilities, and then only reluctantly. Cardiac neurosis can and should be adequately handled by the man in general practice, as well as by the internist or cardiologist, except in those patients with a true anxiety neurosis with cardiac fixation who may eventually have to be referred to the neurologist. Cardiac neurosis, in one degree or another, is so widespread as to demand one's careful attention and sympathetic consideration rather than a belittling attitude, or one of contempt, which it so often calls forth.

Prophylaxis of Postoperative Pulmonary Atelectasis.—According to Bergh, atelectasis in some degree is the most frequent of postoperative pulmonary complications, and it merits the serious consideration of the surgical profession. The most widely used prophylactic procedures are hyperventilation induced by administration of carbon dioxide and postural measures, including frequent changes of position to prevent the accumulation of secretions in dependent portions of the lung and, in cases in which there is copious secretion, postural drainage. As adjuncts to these procedures, various other measures have been suggested. Among these are the avoidance of tight binders that embarrass the respiratory movements, voluntary coughing, the administration of expectorants and the elimination of the preoperative administration of atropine. There is disagreement as to whether or not morphine should be given, but most investigators believe that its use should be restricted to the extent that it does not interfere with the cough reflex. Pain, however, should be controlled. The inhalation of carbon dioxide produces an increase in the rate and depth of respiration and also causes the thorax to be maintained in a state of greater expansion. This distends the lung and tends to open areas of atelectasis. It also produces violent movement of the tracheobronchial tree, tends to dislodge adherent mucus and thus opens the air passages. The effects of carbon dioxide inhalation are transient and disappear when the administration of the gas is discontinued. The three principal groups of patients who require postoperative hyperventilation are those who undergo abdominal operations, those who have excessive bronchial secretion and elderly and debilitated patients. Since the beneficial results of carbon dioxide inhalation are temporary, it is recommended that the hyperventilation be repeated at frequent intervals. In most cases three or four administrations a day are sufficient, but there is a considerable number of patients who require more frequent hyperventilation. It is suggested that each administration be continued over a period of three minutes, with a mixture of 10 per cent carbon dioxide and 90 per cent oxygen.

Office Management of Sterility Cases.—Kliman believes that sterility is found in about 20 per cent of all married women. Two day dysmenorrhea of the nonobstructive type occurs in about 85 per cent of all sterile women. Cure of the dysmenorrhea frequently corrects the sterility, since the two conditions are often of common origin. About 90 per cent of sterile women complain of pain and leukorrhea, and both these symptoms indicate intrapelvic inflammation. General disturbances such as chronic alcoholism, anemia and syphilis should receive appropriate treatment. Inflammatory lesions of the uterus and adnexa should be treated by means of vaginal douches, sitz baths, foreign protein therapy, and electrical cauterization of the cervix. Uterine displacements should be corrected and maintained by means of a pessary. When endocrine disorders are suspected, the use of thyroid, anterior pituitary preparations and the various sex hormone preparations are often of benefit in regulating the menstrual cycle. When the normal menstrual cycle has replaced a previous irregularity, the Dickinson insemination test may be tried after all other treatments have failed to produce the desired results.

Prostatectomy and Transurethral Prostatic Resection.—Davis and Owens believe that transurethral prostatic resection, properly employed in selected cases, is valuable. The majority of opinion indicates that this procedure will partially replace, but will not supplant, prostatectomy. What type and what per-

centage of obstructing prostates may be best removed by resection or by prostatectomy remains to be determined. These questions may be answered only by an impartial analysis of end-results. The chief advantage offered by the transurethral method is a decreased period of hospitalization. Preliminary drainage, preceding resection, however, is just as essential as before prostatectomy. It seems doubtful whether the transurethral method, considering the mortality rate, the immediate functional results and the ultimate functional results, offers the patient as great a degree of assurance of continued health and comfort as does perineal prostatectomy. It is likely that the personal equation will come to be an important factor in answering these questions. Each must compare his own results.

Blood Sedimentation Test.—Grodinsky used Linzenmeier's sedimentation test as modified by Friedlaender in the differential diagnosis of inflammatory pelvic diseases, noninflammatory pelvic conditions, diseases of the urinary tract and appendicitis. From this study he concludes that the blood sedimentation test is a simple and reliable means of diagnosis and prognosis in general surgical conditions, often surpassing the blood count in value. It is of particular value in the differential diagnosis of appendicitis from other pathologic conditions of the lower right quadrant of the abdomen.

Treatment of Cardiovascular Syphilis.—Traynor points out that, in treating an otherwise healthy young adult with primary or secondary syphilis, a so-called routine treatment has its place. A course of arsphenamine or neoarsphenamine injections, a course of mercury or bismuth compounds with rest periods at intervals, constitute the routine, but when such vital organs as the heart, liver or brain are involved one faces an entirely different problem. One should never institute treatment on the basis of a positive Wassermann reaction alone; one must first study the patient and determine the state of his aorta, heart, kidneys and nervous system. The patient may and usually does need many of the therapeutic measures that the non-syphilitic cardiac patient requires. Rest, both physical and mental, digitalis, diuretics, nitrites, morphine, and so on, all have their place. When congestive heart failure is present, all antisyphilitic drugs should be withheld until compensation has been restored. When the usual measures for heart failure have failed to restore compensation, mercury and iodides may be given as a last resort with an occasional good result. In coronary disease, a thorough preparatory course of mercury and iodides should precede the use of the arsenicals. Neoarsphenamine is preferable to arsphenamine. It should be started in small doses, not over 0.1 Gm. If no untoward symptoms develop after the first few doses, the dose may be cautiously increased. An aortic aneurysm of any size can never be cured. In the smaller types an arrest of growth may be obtained. Even in the larger tumors, symptomatic relief may be afforded, possibly as a result of the liberation of adhesions resulting from the mediastinitis or periaortitis.

Progress in Dermatology. H. P. Towle and J. Grund, Boston.—p. 374.

Injection Treatment of Varicose Veins.—Faxon presents the end-results of 314 cases of varicose veins treated by the injection method. Recurrences followed in 63 per cent in an average period of 1.4 years, 25 per cent of the total number showed new varicosities, 28 per cent were relieved of pain, 19 per cent were relieved of edema and 61 per cent of the ulcers were healed. In a large number of the cases the patients' attitude toward the results was more favorable than was deserved. The author's technic was to have the patient sit on the edge of the table with the feet on a chair; injection at two points was ordinarily done at one sitting with an average dose of 1.5 cc. at each point. With the smaller varices the patient was allowed to stand in order to distend the vein during

the injection. In the majority of cases the treatments were started at the junction of the middle and lower thirds of the leg and subsequent injections were given at progressively higher levels. Immediate pressure with a piece of gauze was made over the puncture wound directly following the injection when the needle was withdrawn. Woven supporting bandages were worn during the course of treatment and for two weeks thereafter. Large varicosities above the knee were constricted by wide adhesive strapping after injection. The position of the varicosities was marked out on a stamped diagram of the legs at the first treatment and the site of each injection was marked on this chart following each treatment. When no further varicosities could be found to inject, the patient was instructed to report at the end of three months and further injections were carried out at that time if any unthrombosed veins could be discovered. The author concludes that primary high ligation of the main saphenous trunk, when it is varicose, is a necessary adjunct to the injection method of treatment, if the best results are to be secured. The practice of stripping the vein, in part at least, of its blood before injecting, and restricting the injection solution to the area treated for an appreciable time after injecting will give better results when the larger varicosities are being dealt with. Continued support of ulcer cases over an indefinite period after the lesion has healed is often desirable. Quinine hydrochloride and urethane is the preparation of choice, although exceptions to its exclusive use may arise.

Female Sex Hormones.—Rock concludes that the therapeutic value of the ovarian hormone, at least in the amount in which it can be given to and paid for by patients, is limited, and that the effect of much larger doses is still undetermined. So far, experience with these and other endocrine products gives little assurance that the effect of the hormone on the genital apparatus of women will be the same as on the genital apparatus of rats and rabbits. It has been shown that the so-called luteinizing hormone will relieve certain cases of atypical uterine bleeding. It will certainly not relieve all, and probably will permanently cure only a few. For carefully selected and properly diagnosed cases, it offers a superior method of treatment. It is to be hoped that all practitioners will guard against the unwarranted optimism which blatant advertising of these newer preparations engenders. This iniquitous deception of physicians is especially to be deplored if it tempts them to forget that bleeding from the vagina can be and often is caused not by simple endocrine disturbances but by cancer, which is a mortal disease if not diagnosed early or may become such during a time consuming series of useless but expensive injections of a mysterious endocrine excreted in the urine.

Separation of Symphysis Pubis.—Boland reports nine cases of separation of the symphysis pubis (eight of his own and one of Hoy's), which occurred in 4,800 consecutive deliveries. Four of the cases occurred following normal delivery, two after falls during the prenatal period, and the other two as the result of forceps extraction. Normal deliveries were productive of separated symphyses more often than other agents of trauma in this series. The lesion occurred in one out of every 685 deliveries and is comparatively frequent. Pain and tenderness in the region of the pubic and sacro-iliac joints, peculiar gait and palpable separation at the symphysis are the most common symptoms. Roentgenograms confirm the separation and show sacro-iliac involvement. Treatment consists in the use of a fracture board or Bradford frame together with adhesive strapping, or a swathe sling and traction, to relieve the acuteness of the lesion. Correction of the gaping of the pubic and sacro-iliac

joints is essential for functional results. Cases previously separated will reparate in succeeding pregnancies. Orthopedic follow-up is essential for the relief of symptoms and restoration of function.

*General Hyperthermia with Heat Localization by Radiotherapy in Treatment of Pelvic Inflammatory Disease. W. Bierman and E. A. Horowitz, New York.—p. 218.

Present Status of Allergic Diseases.—Clarke points out that the present status of the allergic diseases would seem to be that practically all cases of urticaria, angioneurotic edema, seasonal hay fever, and most of the cases of uncomplicated asthma must be included in this category, that most cases of eczema not caused by direct irritation or inflammation of the skin are allergic, that many cases of chronic rhinitis and recurring bronchitis are of a similar nature, and that probably most cases of mucous colitis and some cases of indefinite gastrointestinal symptoms including pain, nausea, and tenderness are due to allergic lesions. The suggestion has been made that pylorospasm and gastric and duodenal ulcer may have an allergic origin. In the nervous system, migraine is commonly caused by allergy. Ménière's disease may be another manifestation of the same condition, and there is a probability that certain cases of epilepsy are of a similar nature. Certain acute arthritides and some cases of chronic arthritis are probably allergic. The allergist cannot cure all chronic incurables, but he certainly can cure certain cases previously considered incurable. The allergist does not ask that every case of bronchitis or abdominal pain be put through a course of skin tests, but he does ask that cases of asthma, eczema, urticaria and hay fever be given this opportunity of relief, that, when migraine has been present for years after eye strain, constipation and pituitary involvement have been eliminated, when chronic indigestion has made life miserable and medical aid has been unavailing, when a running nose persists in spite of the best local medical and surgical care, and when a child shows signs of beginning epilepsy without evident cause, the family physician offer these patients the chance of relief given by an appreciation of the possible allergic nature of these diseases, and refer them to the allergist for careful study.

Hyperthermia in Treatment of Pelvic Inflammatory Disease.—Bierman and Horowitz treated twelve patients presenting various pelvic inflammatory diseases with localized hyperthermia produced by the radiotherm. Five cases of subacute salpingitis and two postabortive pelvic infections improved rapidly. Three cases of chronic salpingitis improved. A case of gonorrheal arthritis was cured after one treatment. In one case of subacute salpingitis, a tubo-ovarian abscess requiring operation developed after radiothermy treatment. One large tubo-ovarian abscess was not much affected by two treatments. One drained abscess resolved rapidly. In order to produce a simultaneous increase of body temperature with a still higher increase in the temperature of the vagina, the authors employed the following method: With the patient in place between the condenser plates of the radiotherm, an electrode is placed in the vagina. This electrode is connected, through an ammeter, to a small auxiliary metal plate suspended near one of the large condenser plates of the radiotherm. Under these conditions the electrical field produced in the region between the electrode and the condenser plate opposite to the one near which the auxiliary plate is suspended is considerably higher than it is at any other part of the body. When the region to be heated is bilateral, the pick-up plate is placed first on one side and then moved to the other. With a pick-up plate of about 300 sq. cm. the distance between the pick-up and the condenser plate varies from 10 to 30 cm. The readings on the radio-frequency ammeter usually vary from about 1 to 2 amperes. With this technic it has been possible to develop temperatures

ranging from 110 to 116 F., as indicated by a mercury thermometer inserted in the vaginal electrode, while the temperature in the mouth is registered between 101 and 104 F.

Pellagra.—Gardner states that acidosis, avitaminosis and anemia should all be considered in pellagra, instead of avitaminosis alone. The diagnosis of pellagra is usually made from the typical erythema, which is symmetrical and resembles sunburn, is on exposed surfaces, and is usually a duller red than erysipelas or sunburn. This progressively becomes darker until a dirty black chapped appearance is found. At times the eruption is macular. The preeruptive diagnosis is seldom made, but the following symptoms should cause one to think of pellagra: 1. Symptoms of neurasthenia and starvation acidosis—such as air hunger, collapse, great weakness and cardiac distress. 2. Symptoms that would suggest an incipient tuberculosis, but afebrile and with a negative lung examination. 3. History of an acute severe illness during which millions of erythrocytes were destroyed, as in acute malaria and lobar pneumonia, in which the oxygen carrying cells were diminished and the carbon dioxide increased. 4. History of indigestion, due to gallbladder infections, appendicitis, genito-urinary infections, bringing on a starvation acidosis, which, coupled with a food deficiency, due either to poverty or to digestive weakness, leads to anemia. In the treatment of pellagra, the following measures are indicated: (1) the relief of starvation acidosis by diet or by surgical removal of the entity interfering with digestion; (2) the removal of infected teeth and drainage of the sinuses; (3) the eradication of malaria and intestinal parasites; (4) the control of diarrhea by opiates and bismuth compounds; (5) the administration of sulpharsphenamine in 0.4 and 0.6 Gm. doses, which may arrest the progress of pellagra cases in which cerebrospinal symptoms are present, and (6) a balanced diet after infection has been removed and the conditions which interfere with hydrolytic cleavage of carbohydrates and suboxidation of the proteins due to hypochlorhydria, lack of bile—pepsin, and so on are obviated.

Understanding and Treatment of Nervous Child. H. F. Corson, Providence.—p. 21.
Report of the Milk Commission of the Providence Medical Association. R. C. Bates, Providence.—p. 26.

Tribrom-Ethanol Anesthesia.—Migliaccio states that tribrom-ethanol is used merely as a basal anesthetic, but large

series of cases show that, in approximately 30 per cent of cases, the operation can be completed without the aid of supplementary anesthesia. If the anesthesia is deeper than desired, carbon dioxide, strychnine, caffeine, ephedrine or epinephrine can be used to hasten elimination and lighten anesthesia. In extra-abdominal operations, when supplementary anesthesia is necessary, local infiltration of procaine hydrochloride or the administration of gas-oxygen suffices. In abdominal operations, somewhat more nitrous oxide is used and greater relaxation can be obtained if the anesthetist administers about 1 ounce of ether through the gas machine just previous to the opening, and, again, before the closing of the peritoneum. The patients rarely realize that a supplementary anesthetic was administered. Tribrom-ethanol as a basal anesthetic can be used in practically every type of operation, but it is especially advantageous in nervous individuals, in operations about the head and neck, and in operations requiring considerable time. It offers special inducements to the gynecologist in combined vaginal and abdominal operations, because in these cases the vaginal work can be done with little or no supplementary anesthesia and gas-oxygen need not be given until the abdomen is prepared. In operations about the mouth there is no face mask to obstruct and interfere with the surgeon. Tribrom-ethanol is ideal in operations for hyperthyroidism, because in these cases the patient is asleep before he is even aware of the fact that he is being anesthetized, thus avoiding a great deal of unnecessary excitement and anxiety for the patient. Tribrom-ethanol anesthesia is contraindicated in advanced disease of the liver or kidneys, obesity, ulcerative diseases of the rectum, extreme cachexia, dehydration and debilitated elderly patients.

Scalenotomy.—Clyne states that the severing of the scalenus muscles allows the first two ribs to sag and to a certain extent decreases the respiratory excursion of the first three ribs, thereby inducing a degree of rest in the region of the apex of the lung. In his series of sixty-six cases of scalenotomy, the phrenic nerve had been severed in twenty-two from six months to three years previously, and the resulting improvement had come to a standstill. Scalenotomy resulted in further improvement in twelve of the twenty-two cases. There were three cases of tuberculosis, chiefly apical, associated with asthma, and, because it was believed that full action of the diaphragm was indispensable to respiration in this complication, the phrenic nerve was not cut but scalenotomy alone was done. There was clinical improvement in two of these three cases. The combined operation was done in forty-one cases, with resulting improvement in twenty-five. In two of these cases pneumothorax had been established for a year or more, but with no improvement because of broad apical adhesions, and both of these cases were improved by the combined operation.

Placenta Accreta.—Smith reports a case of placenta accreta in a woman, aged 31, on whom a complete necropsy was performed. The characteristic features of this abnormality are partial or total absence of the decidua basalis and invasion of the musculature of the uterus by chorionic villi. In addition to repeated or too vigorous curettage, endometritis, submucous fibroid and previous manual removal as etiologic factors, the author's case adds the possible significance of previous cesarean section. The manual removal of the placenta at the time of

cesarean section would further increase the possibility of a hypoplasia of the endometrium, with a resulting tendency to placenta accreta. A review of the literature gives perforation and rupture of the uterus, hemorrhage, shock and sepsis as some of the causes of the condition. The author's case adds the danger of embolism from venous thrombosis. In the presence of an attached placenta with no descent of the cord and without bleeding, aseptic exploration under anesthesia should be made to determine the subsequent procedure. If no line of cleavage can be demonstrated, hysterectomy should be done.

Osteomalacia.—Wampler states that deficient calcium in the diet, lack of exercise, bound feet, dark rooms, bad housing and lack of sunlight are contributing factors in osteomalacia. While children born of osteomalacic mothers do not show gross signs of rickets, Maxwell has shown by section of the bones that fetal rickets does exist. It is a disease largely of the female but it is by no means unknown in the male. The treatment at present is cod liver oil with viosterol. Some form of calcium should be prescribed along with this. Irradiated foods and viosterol can help much by supplying larger quantities of the vitamin without giving excessive quantities of cod liver oil. Ultraviolet radiation and sunshine are of great help. In the prevention of the disease, better food and more sunshine for all women should be urged and especially stressed for pregnant and puerperal women. If numbness occurs, 1 ounce (30 cc.) of cod liver oil should be taken daily.

Vomiting in Infancy and Childhood.—Jones points out that 20 per cent of vomiting in infancy and childhood may be due to intussusception, pyloric stenosis, pylorospasm, appendicitis, brain tumors, brain abscesses, hydrocephalus, acidosis, dentition or acute infections. He gives the characteristic symptoms in each condition and states that habit vomiting or rumination is not an infrequent type of chronic vomiting in the neurotic child. It is frequently preceded by sucking of the fingers. The characteristic features are the habitual movements of the lower jaw, to and fro movements of the tongue, and apparent attempts to swallow after feeding. The regurgitant type of vomiting is never forcible. Taylor and Morse report good results from tying up the lower jaw; others report good results from tying the hands so that the fingers cannot be placed in the mouth, from attracting the attention of the baby immediately after nursing by ringing a bell or by a rattle, or even from the use of a pacifier as a means of a diversion. The semierect position after feeding is likewise said to produce good results. Often the use of thick cereal feedings will promptly control the vomiting when the thinner liquids cannot be retained. Vomiting in the new-born may be due to gastro-intestinal irritation from swallowing maternal discharges. Attempts to force too early feedings will often cause vomiting in the new-born. It may also be due to toxemia and may frequently result fatally in the offspring of toxemic mothers. Vomiting in the new-born may be due to congenital defects in the gastro-intestinal tract. Vomiting is a prominent symptom in peritonitis from acute pyogenic infections in the new-born.

*Obstetric Anesthesia and Analgesia in General Practice. A. E. McMahon, Glenwood City.—p. 102.

Infections of Upper Respiratory Tract.—Schwartz observed, at a children's hospital during a period of ten years, that infection of the upper respiratory tract is the largest single cause of death in the immature infant after the first two weeks of life. In an infants' hospital limiting its patients to nutritional problems, it was responsible for the death of 25 per cent of the immature infants. In a series of 157 immature infants, 45 per cent of the deaths were due to infection of the upper respiratory tract. In thirteen instances of death from pneumonia confirmed by necropsy, the respiratory infection developed after a two weeks stay in all but two instances. Children's hospitals, because of their unusually high mortality rate from infection of the upper respiratory tract, are not an ideal place for the care of immature infants. An obstetric floor of a general hospital, or supervised homes using the Speedwell technic, should give a lower incidence of respiratory infection and a lower mortality rate among immature infants.

Otitis Media.—Harkins points out that, like appendicitis, otitis media is to be feared because of its complications. Meningitis, brain abscess, lateral sinus thrombosis, and even lung abscess are the lurking possibilities one should keep in mind when undertaking the treatment of an innocent looking, inflamed middle ear. Otitis media is a common complication of all contagious diseases and diseases of the upper respiratory tract in childhood and early adult life. It is considered lightly by the public, by the family physician and oftentimes by the specialist. Its proper treatment consists of early diagnosis, early drainage and attention to the general well being of the patient. Removal of diseased tonsils and adenoids and the segregation and control of infectious diseases decrease materially the incidence of otitis media.

Ocular Manifestations of Focal Infection.—Trumbo states that iritis and retrobulbar neuritis are the two most common ocular diseases due to focal infection. The less common ocular manifestations of focal infection are corneal ulcers, blepharitis and tarsal cysts, conjunctivitis, episcleritis, increased lacrimation, optic neuritis and atrophy, recurring retinal hemorrhages, choroiditis, retinitis, vitreous opacities and cataract formation and disturbances of ocular motility. Focal infections as causes of ocular diseases must be considered as next in importance to syphilis and tuberculosis. More careful examination, especially dental, must be made, the ophthalmologist directing the investigation and retaining control of the patient. Conservation of vision and improvement in the general public health program of preventive medicine will result from the elimination of foci of infection that will be found as a result of more careful consideration of the focal causes of ocular diseases. The more general use of the intradermal tuberculin test is urged as a diagnostic aid in suggestive cases, after foci of infections are removed and no improvement is shown.

Obstetric Anesthesia in General Practice.—McMahon believes that morphine or pantopon and scopolamine in small doses in the first stage, with ether or chloroform inhalations to the obstetric degree in the second stage, constitutes a satisfactory obstetric anesthetic in the majority of normal cases. The Gwathmey method, or synergistic analgesia, is practicable and satisfactory. Twilight sleep is not to be recommended for use in the home. Sodium amytal, while quite satisfactory in hospital practice, is not well adapted to home use. Spinal anesthesia is unsurpassed for forceps deliveries, episiotomy and perineal repair but can hardly be recommended for routine use because of the frequent loss of the auxiliary forces following its employment. Caudal anesthesia has also been used to a certain extent in obstetrics. The results are not as successful as those obtained

with spinal anesthesia. The chief objection is the fact that the solution must be prepared fresh for each case. Furthermore, deformities in the sacral hiatus are quite frequently encountered, which make the administration difficult or impossible. The use of nitrous oxide or ethylene and oxygen is highly satisfactory, but their use is necessarily restricted to hospital practice.

Periodic Group of Disorders in Childhood.—Wyllie and Schlesinger state that in the periodic group of disorders in children are included bilious attacks, cyclic, ketogenic or acetone-mic vomiting, recurrent pyrexial attacks and migraine. From a study of eighty cases, they collectively regard these disorders to be of common origin. The periodic attack is manifested clinically by a syndrome composed of vomiting, abdominal pain, headache and fever. A report is made of the occurrence, in some cases of vertigo, of raised blood pressure, lapses of consciousness and convulsions. The authors discuss the influence of heredity and the prevalence of the periodic group of disorders in families constitutionally predisposed, and the relationship between these disorders and allergy; they compare the effects of a ketogenic diet and the results of liver function tests in normal children and in those subject to the periodic syndrome, and they conclude from their investigations that the primary factor underlying the occurrence of these disorders in children is of nervous origin. The treatment of the periodic group of disorders is confined to preventive and palliative measures, as no specific therapy can overcome the factor of nervous instability on which they depend. Much importance has been attached to dietetic modifications, of which the low fat-high carbohydrate ratio is the most popular. The giving of dextrose, from 2 to 3 drachms (8 to 12 Gm.) three times a day, has been extensively advocated as a beneficial measure in preventing attacks. In many cases the authors have noted as much benefit from a normal well adjusted diet as from any of the modifications. A ketogenic diet has recently been advocated for the treatment of migraine. Baborka reports that in fifty patients between the ages of 16 and 66 the attacks were controlled in fourteen, and that twenty-five were benefited. In those cases in which a personal or a familial indication of allergy occurs, it is advisable to test for skin reactions and to try the effects of eliminating from the diet those articles to which a hypersensitivity is shown. The maintenance of regular evacuation of the bowels is of major importance. Constipation, with an excess of mucus, is usual and, presumably, has an adverse effect on the liver function. The most suitable remedies for this purpose are sodium bicarbonate, rhubarb powder or syrup of senna, given in small doses three times a day. Sepsis of the tonsils or sinuses should be treated when present. For the treatment of obstinate headaches, small doses of dried extract of thyroid and phenobarbital are sometimes efficacious. Errors of refraction must be corrected. Severe cases of cyclic vomiting are best treated by rectal and intravenous injections of saline and dextrose solution. Certain general principles requiring attention in the care of children susceptible to the periodic syndrome are the avoidance of excesses of mental or physical exhaustion or excitement.

Vector of Tropical Typhus.—Roberts and Tonking state that investigation of the fauna of houses from which tropical typhus has been reported suggested *Rhipicephalus pulchellus* and *R. sanguineus* as possible vectors. Guinea-pigs, when injected with emulsified *R. sanguineus* taken from a house in which a case of tropical typhus had just occurred, gave positive reactions pathognomonic of the disease, both clinically and histologically. The virus was passed through further guinea-pigs, which also gave typical reactions. The dog is the main host of the incriminated tick, but it will readily feed on human beings. The regular deticking of domestic dogs is strongly advocated.

*Excretion Urography. R. H. Mitchell.—p. 62.
Trachoma Prophylaxis. F. Lavery.—p. 77.

Excretion Urography.—Mitchell points out that the advantages of excretion urography are, chiefly, its simplicity and its freedom from instrumentation and risk to the patient. The advantage of obtaining bilateral pictures cannot be overestimated. Excretion methods often eliminate the necessity for instrumentation on more than one side. Excretion urography gives better cortical definition than retrograde urography; further, it is a physiologic method of viewing the urinary tract and gives a useful indication of the kidney function. It is especially indicated in cases in which it is impossible or dangerous to use instrumental urography. It is indicated in patients presenting kidney symptoms who have not reached the age of puberty, and in pregnancy. It is of value in obstructive types of hydronephrosis, particularly those caused by ureteral calculus, and it is the only way of disclosing congenital abnormality in a large percentage of cases. The disadvantages are that the method is expensive and that it gives a less clear definition of the urinary tract than instrumental urography. The author has used skiodan since November, 1930, in his technic of excretion urography. The patient is purged thirty-six hours before urography, and a mild laxative is again given twelve hours before the injection. The diet is restricted during the entire preparation, and the liquid intake during the twelve hours immediately prior to the injection is decreased as much as possible; a cup of tea and a biscuit are all that is given on the morning of urography. The patient is put on the table and 50 cc. of skiodan solution, warmed to body temperature, is injected into the cubital vein by means of a 20 cc. syringe fitted with a two way tap, to one limb of which is attached a needle, the other being connected by rubber tubing to a glass vessel containing the solution. The entire quantity is injected in two or three minutes. A "straight" roentgenogram is invariably taken as a control before injection. The first skiodan roentgenogram is taken ten minutes after injection, the second twenty minutes, and the final exposure thirty-five minutes after the injection. This is the routine method when information is required not only of an anatomic nature or about calculi, displacements and such anomalies, but also of the functions and dynamics of the urinary tract. If anatomic information alone

is required, a single exposure twenty minutes after injection generally suffices. If the three exposures are negative, owing to dysfunction of one or both kidneys, a further exposure is taken one hour after the injection. When the lower third of the ureter is suspected of pathologic changes, or in cases of suspected calculus in the lower part of the ureter, the bladder is emptied before the second and third and any subsequent exposures so that it may not obscure the pelvic portion of the ureter because of the skiodan secreted into it. The technic with iopax and an iopax derivative is the same save that with the former the injection is double the quantity and is extended over fifteen minutes.

Phthisis Pulmonalis.—Griffith and Munro obtained cultures of tubercle bacilli from the sputum of 222 patients with pulmonary tuberculosis. The strains obtained from 212 of the patients exhibited the characters of tubercle bacilli of the human type, 209 of the strains belonging to the eugonic human and three to the dysgonic human variety. The latter were tested on the rabbit and proved slightly virulent for this species. The twenty strains from the remaining ten cases were identical in cultural characters with bovine bacilli. All these strains were tested on the rabbit by subcutaneous, and in some instances also by intravenous, inoculation and produced in one or more animals rapidly fatal general tuberculosis indistinguishable from that which follows inoculation of standard bovine tubercle bacilli. One strain was tested on the goat and proved fully virulent for this species also. Of the ten patients suffering from bovine phthisis, three died and necropsies were made on two. In one instance the patient died before the type of infecting bacillus had been determined, and only a partial necropsy was made. The channel of the infection was not determined. The occurrence of enlarged glands before the onset of phthisis indicated that the channel of infection was probably the alimentary canal. In the other necropsy, no tuberculous lesions were found in the neck glands, abdominal organs or lymph nodes. The tuberculous disease was apparently confined to the thoracic cavity. There had been clinical indications of a cerebral tuberculoma in the left frontal lobe, but this could not be confirmed as permission to examine the brain was not granted. The intertracheobronchial glands, particularly the right, showed caseation, but there was no lesion in the lung that could be regarded as primary, the distribution of the pulmonary lesions suggesting rather a root spread type of disease. The anatomic evidence as to the portal of entry of the bacilli was inconclusive, but there were indications that infection with the bovine type of bacilli was through the respiratory tract, the vehicle of infection being dust from the hides of cows or arising in the stable, or droplets sprayed by a cow suffering from tuberculosis of the lungs.

Pleural Empyema in Pyonephrosis.—Howard states that cases of pyonephrosis rarely give rise to severe pulmonary complications, only 5 cases out of a series of 180 being so complicated. Other cases of subphrenic acute infective processes, notably subphrenic abscess, often give rise to severe pulmonary complications, 67.44 per cent being accompanied by effusion of some kind, and 27.9 per cent by purulent effusion. The explanation of this apparent inconsistency is: (1) the long period usually elapsing between the formation of a subphrenic abscess and its detection, as contrasted with the usual early diagnosis

of pyonephrosis; (2) the upper abdominal peritonitis associated with subphrenic abscess and the resulting immobility of the diaphragm, and (3) the tough fibrous capsule of the kidney exerting a limiting effect on the spread of infection. Patients presenting acute pyonephrosis who are left untreated for long periods are likely to develop severe intrathoracic complications.

Human Bundle-Branch Block.—Tung and Cheer made a study of all electrocardiograms showing either right or left bundle-branch block from 1921 to April, 1932, and of the corresponding clinical records. They analyze ten cases of right bundle-branch block, in which the broad initial ventricular deflections are downward in lead I and upward in lead III, and six cases of left bundle-branch block, in which the opposite changes are found. The comparative frequency of right bundle-branch block, which is generally considered the rare type, is noted. Of the ten patients showing right bundle-branch block, seven had rheumatic heart disease, in six of which definite mitral stenosis was present. Arteriosclerotic and congenital heart disease occurred in the other three. Of the six patients showing left bundle-branch block, all had hypertensive or arteriosclerotic cardiovascular disease. Three patients with mitral stenosis, whose first electrocardiograms showed right ventricular preponderance, later developed right bundle-branch block. The authors discuss the possible significance of such spontaneous electrocardiographic alteration. The predominant association of right bundle-branch block with mitral stenosis, in which the right ventricle bears the chief brunt, and the exclusive occurrence in their cases of left bundle-branch block in hypertensive or arteriosclerotic cardiovascular disease in which the left ventricle receives the chief damage, are good corroborative evidence in favor of the modern conception of bundle-branch block advanced by Wilson, Oppenheimer, Barker and their associates.

Choleraic Diarrhea.—Tootell gives the symptoms and treatment of the four stages of choleraic diarrhea. The symptoms in the primary stage are elevation of temperature, headache, diarrhea, nausea, with possibly a history of having eaten raw vegetables or the drinking of unboiled water. The treatment consists of the usual diarrheal measures: rest; liquid diet. In evacuation, at least three of the following symptoms are present: purging, vomiting, abdominal pain, pain in the lower extremities, weak pulse, sunken eyes and shrunken skin. The general treatment in this stage of the disease is saline solution administered intravenously if the pulse is weak, and subcutaneously if its volume is good, 4 Gm. of kaolin and 0.3 Gm. of sodium bicarbonate every three hours by mouth, rest, and nothing but liquids until the vomiting and purging cease. During the stage of collapse the symptoms are those of evacuation except that the pulse is imperceptible, the skin is cold and clammy and the temperature is subnormal. In this stage the treatment is the intravenous use of saline solution until the pulse drops to below 90 or the patient has received 1 pound of saline solution for every 15 pounds of body weight. In the male this averages about 4,000 cc. and in the female about 2,500 cc. Kaolin, 4 Gm., and sodium bicarbonate, 0.3 Gm., is given by mouth. Compound tincture of camphor may be given for the pain, but some authorities consider it contraindicated. A liquid diet should be maintained. In the reactive period weakness, dizziness, anorexia and a desire to remain quiet and rest are the pre-

dominating symptoms. General treatment is usually dietetic, beginning with liquids and working gradually into a soft and finally a general diet. Kaolin should be reduced in amount or eliminated.

- Sterilizing Action of Saturated Monobasic Fatty Acids on Putrefactive Bacteria, *Bacillus Typhosus* and *Vibrio Cholerae*. S. Tetsumoto.—p. 73.

Serodiagnosis of Syphilis of Mothers.—Nakayama made a serodiagnosis of the blood of 303 pregnant women. He found that the blood of the mother before and after childbirth and the blood of the child have little diagnostic value for syphilis. One should suspect syphilis if these bloods are strongly positive in the Wassermann, Murata and Meinicke (turbidity) reactions. The difference between the specific reaction of syphilis and the nonspecific reaction during the period of confinement and childbirth cannot be found by the complement fixation reaction using the freezing point method. The parturient function causes a remarkable change in the reactive substance as determined by Murata and Tamiya's precipitation curve method and proved in the blood of the mother but not in that of the new-born infant. The antigox hemolysin in the human blood, which Gewin stated appears six months after birth, was not found in the blood of the new-born, regardless of the presence or absence of the syphilitic reactive substance. In spite of the variation in the reactive substance found before and after childbirth by Murata and Tamiya's precipitation curves, no change in the hemolytic value due to the parturient function was found in this hemolysin. It was proved that the reactive substance appearing in the precipitation curves before and after childbirth underwent a remarkable change in the blood showing a negative Wassermann, Murata and Meinicke (turbidity) reaction. In the author's investigation, 7.26 per cent of the women were found to be infected with syphilis.

Flocculation (Ramon).—In order to determine whether flocculation is a specific reaction between diphtheria toxin and antitoxin, Terao tested the reaction between Martin's bouillon, in which no diphtheria bacilli were planted, and normal horse serum or diphtheria serum, and also the reaction between diphtheria toxin and normal horse serum, all of which proved negative. But a remarkable flocculation was found between the diphtheria toxin and diphtheria antitoxin, as reported by Ramon. Diphtheria toxin, when subjected to the influence of a diastatic ferment, entirely lost its toxicity. This detoxicated toxin had no immunogenicity against the guinea-pig, but it caused the same initial reaction as the original toxin. When diphtheria toxin was added with glacial acetic acid, the toxin moved into the precipitate. The supernatant fluid, although it was absolutely nontoxic against the guinea-pig and had no immunogenicity, often caused the same flocculation as the original toxin. Shiga's dysentery bacillus toxin, tetanus toxin and Dick's toxin, which were obtained by cultivation in Martin's bouillon, caused flocculation with diphtheria antitoxin. The property of the product of the reaction was nearly the same as that of the reaction between the diphtheria toxin and diphtheria antitoxin. Diphtheria toxin caused flocculation with Shiga's antitoxic serum. The author observed that freezing and thawing of the diphtheric serum caused a decrease of its antitoxic value, but entirely the same flocculation as in the case of the original serum; that is, substances in the diphtheric serum participating in flocculation had no relation to the antitoxin. No flocculation was caused between the purified Shiga bacillus toxin and Shiga's antitoxic serum obtained from a goat immunized with the purified Shiga bacillus toxin, but the original toxin caused a remarkable reaction. The author con-

cludes that Ramon's flocculation may probably be a reaction between the metabolic product of diphtheria bacilli and the antibody against it.

- Gastric Juice in Treatment of Pernicious Anemia. P.-E. Morhardt.—p. 294.

Test for Diagnosis of Pregnancy.—Masciottra and Martinez de Hoz present a preliminary report on a biochemical method based on the facts that prehypophyseal hormone increases cholesterolemia and that the urine of pregnant women contains the prehypophyseal hormone. It was found in a series of experiments that the injection of urine of pregnant women into guinea-pigs of either sex produced, within the first twenty-four hours, an increase of cholesterol in the blood amounting to from 30 to 50 per cent. The reaction was positive at various stages of pregnancy. In a control series of experiments it was found that the urine of nonpregnant women (surgical control) did not produce the increase of cholesterol observed in the other experiments. Slight variations of less than 5 per cent were observed in a few instances, which may have been due to error in colorimetric readings. The method used in these experiments was as follows: Ten cubic centimeters of urine obtained from the fasting patient by catheterization was mixed with 25 cc. of sulphuric ether. After the mixture had been shaken and decanted, 10 cc. was injected into a guinea-pig. After twenty-four hours, blood was withdrawn from the heart of the animal with a syringe containing crystallized potassium oxalate, and its cholesterol content was determined by the method of Grigaut, described by Grigaut and Achard in the *Revue médicale-chirurgicale des maladies du foie*, March-April and July-August, 1928 (obtainable at the Surgeon General's Library, Washington, D. C.). This test of hormone hypercholesterolemia is considered positive by the authors if the blood cholesterol of the guinea-pig is increased 25 per cent. They think the test has several advantages over the Aschheim-Zondek reaction. The test animal is easier to procure, as it may be male or female, sexually mature or immature, and of any age or weight. The withdrawal of blood does not necessitate killing the test animal. The technic is simple and the test can be performed in twenty-four hours.

- Phlebocardiac Reflex. J. Louvel.—p. 693.

Gastric Complications Following Left Phrenicectomy.—Bernard and his associates state that a study of the literature shows that gastric complications following left phrenicectomy are rare. Most often they are slight and associated with a simple aerophagia due to distention of the stomach, which has ascended following the ascension of the diaphragm. In exceptional cases, owing undoubtedly to predisposing conditions, the ascent of the stomach produces a torsion, and a grave syndrome of volvulus manifests itself. Such a case was seen by the authors; an old perigastric adhesion resulting from an ulcer had caused a tilting of the stomach because of the ascent of the hemidiaphragm following phrenicectomy. The necropsy showed a stomach folded double, having the cardia and the pylorus very near each other and in juxtaposition to the colon, and producing at the same time a gastrocolic ectopy and a torsion of the stomach as in diaphragmatic eventration. In this way the gastric volvulus gave rise to a syndrome resembling that of pyloric stenosis. It would be wise, before performing a left phrenicectomy, to undertake a detailed interrogation of the patient and a complete exploration of the stomach, including a roentgenologic examination, in order to discover any latent gastric lesion capable of giving rise to these dangerous mechanical deviations of the stomach. In the few cases reported, the results of interventions on volvulus of the stomach resulting from phrenicectomy were unsatisfactory. This may be due to the fact that they were performed on tuberculous patients, who show a particular susceptibility to grave abdominal operations.

Treatment of Fracture of Spinal Column.—Jimeno-Vidal describes Böhler's method of treatment for fractures of the vertebral column. The reduction is facilitated by local anesthesia given according to the method of Schmek. With the patient in lateral decubitus, a lumbar puncture needle is inserted at a point 6 cm. from the apophysis of the injured vertebra (to the right if the patient lies on the right, to the left if he lies on the left) on a line perpendicular to the vertebral column, and introduced at an angle of 35 degrees toward the fractured vertebra, and 5 cc. of a 1 per cent solution of procaine hydrochloride is injected directly into the hematoma of the fracture focus. If the needle is bloody when withdrawn, it indicates that the hematoma was located and an additional 5 cc. of the procaine solution is injected in the same spot; if it is not bloody, one must try again to locate the hematoma. For the reduction, the patient is placed in prone decubitus so that the groin is at the edge of the examining table. The upper part of the trunk is raised 25 or 35 centimeters and the head and arms are placed on another table, so that the trunk is suspended between the two tables. A cushion is placed under the ankles, and the legs are strapped to the table in two places. In this position a hyperextension of the spine is obtained. After a few minutes the upper part of the spine is raised still more by putting a box under the patient's arms. At the end of fifteen minutes, approximately, the gibbosity has disappeared completely and the vertebral column is in hyperlordosis. Without the position of the patient being changed, a plaster cast is immediately applied. It should extend anteriorly from the manubrium to the pubic symphysis and posteriorly from the first dorsal vertebra to the sacrococcygeal articulation, space being left on the sides to permit free movement of the arms and flexion of the legs to a right angle. The maintenance of the position of reduction depends on the support given to the manubrium, the pubic symphysis and the point of maximum lordosis. The plaster cast must be retained until consolidation is complete and the vertebral column has recovered its capacity of support. This requires a minimum of twelve weeks in benign cases; in more severe cases, sixteen weeks or more is required. To prevent circulatory disturbances, muscular and osseous atrophy and articular rigidity, the patient is permitted to walk from the outset of the immobilization and several times daily performs exercises consisting in extension of the arms and legs in all directions, flexion of the knees, flexion and extension of the trunk while lying prone on a bed with the pubic symphysis on the edge of the bed, and flexion of the legs in dorsal decubitus. An especially important exercise consists in carrying a sandbag on the head for fifteen or twenty minutes, the weight of which is gradually increased from 5 to 40 Kg. When the plaster cast is removed, the elasticity and supporting power of the vertebral column are as good as they were prior to the injury.

Arthrodesis of Hip in Treatment of Coxalgia.—Delahaye and Courvoisier think that every formerly coxalgic hip which is unstable and painful in walking benefits by arthrodesis. Extra-articular arthrodesis is the simplest method but is advantageously replaced by mixed arthrodesis if large freshening of wound surfaces is required for a good consolidation and if accessible residual lesions persist in the interior of the articulation. The curettage and emptying of these lesions is indispensable to a rational intervention. A residual lesion must be sharply differentiated from chronic coxalgia; in the latter, opening of the joint constitutes a serious error. Arthrodesis by freshening of the wound is used only in certain extracotyloid pseudarthroses with total disappearance of the head and neck of the femur and marked ascent of the femoral stump. An ordinary coxalgia in evolution, in an adult with good general resistance and without other serious active focus, is also benefited by arthrodesis pro-

vided the hip is kept quiet long enough for the local symptoms to be reduced to a minimum. In rare coxalgias that terminate favorably, usually those secondary to a psoas abscess originating in Pott's disease, arthrodesis may be unnecessary. The intervention is contraindicated during the slightest febrile attacks and in the presence of an active abscess or fistula. The para-articular form of arthrodesis is preferred in coxalgia in evolution. The intervention shortens the period of evolution and arrests the spread of the lesions; besides a successful graft, in special cases, an intra-articular osseous ankylosis may take place. Arthrodesis in coxalgia in evolution in children is still in the stage of research. Lasting coxalgias, with slow, progressive destruction and without abscesses or fistulas, often benefit by prudent intervention after drying of the hip. Juxta-articular arthrodesis is often the best method, but in cases in which the freshening of large surfaces by removal of the iliac graft and the danger of hematoma are feared, the para-articular method is preferable. Below the age of 12, the para-articular arthrodesis should be of the external ilio-diaphysary type to avoid intratrochanteric pseudarthrosis. During the first year of evolution, arthrodesis of any type is contraindicated. Arthrodesis during the period of freely evolving abscesses or fistulas in the second year is also contraindicated. In the third year of the evolution of a normal coxalgia, when the abscesses and fistulas have ceased, the osseous lesions are circumscribed and recalcification has started, the indications are clear in three groups of cases. When the roentgenogram in confirmation of the clinical examination shows a loose intra-acetabular or extra-acetabular pseudarthrosis with large destruction, para-articular arthrodesis is indicated. Certain coxalgias evolving with little destruction and tending toward a compact pseudarthrosis terminate in excellent condition after from two to two and one-half years. Usually they tend to progressive flexion-adduction and benefit by extra-articular arthrodesis performed at that moment. Others spontaneously attain an osseous ankylosis in good position, making intervention unnecessary. Indications are less precise in certain benign coxalgias, which, in their third year, exhibit a minimum of destruction and an extensive mobility, and in certain pseudarthroses with regular excavation of the acetabulum and conservation of the head, manifesting the same advantages. If stability, mobility and painlessness seem probable during the last year of evolution of these cases, it is best to let the patient benefit by the articular mobility and to intervene later only if a positive indication arises. In invasive, rapidly evolving coxalgias, the general resistance of the patient is usually poor, toxemia exists and intervention in any form is useless and dangerous. Exceptionally, the coxalgia may be localized and the general resistance be fairly good; in this event an intervention at a distance may be considered, but only with great prudence.

Pulmonary Mycoses Caused by *Penicillium Crustaceum*.

—Aimé and his associates report a case of pulmonary mycosis caused by *Penicillium crustaceum*. When the patient, a woman aged 41, was first seen a diagnosis of chronic pleuropulmonary tuberculosis was made on the basis of the anamnesis, a cough, dyspnea and expectoration and the roentgenographic symptoms of parenchymatous lesions with pleural adhesions and calcification of the right base. No tubercle bacilli were found in the sputum. In the five years that followed, the patient was seen several times and received iodine treatment, which alleviated the cough and dyspnea, but the loss of weight continued and an extension of the pulmonary signs appeared on auscultation. When the patient was seen again ten years after the first examination, the cough and dyspnea were greatly aggravated, the expectoration was abundant, mucopurulent and brick red, and the temperature was elevated. The roentgenogram showed a suspended hydro-aeric image of the right base, presenting the character of a lung abscess. At this time, an examination of the sputum by one of the authors, who was dissatisfied with the diagnosis, showed mycelial filaments on direct examination and the presence of *Penicillium crustaceum* in cultures. Under the influence of an intensified iodine treatment and of administration of an antimycotic vaccine, the clinical symptoms receded and the roentgenographic aspect of the lung returned to normal with the exception of a slight pleural thickening of the right base. Only two other cases of pulmonary infection with *Penicillium crustaceum* are reported in the literature. The case.

is further interesting because of the slow development of the pulmonary lesion, which probably started with a dry pleurisy at the age of 19, and of the phase of ulceration. The authors think that systematic examination of the sputum would reveal more cases of pulmonary mycosis, and particularly of infection with *Penicillium crustaceum*.

Crisis in Cell Respiration. C. Oppenheimer.—p. 578.

Treatment of Anemia.—Morawitz calls attention to certain shortcomings of the modern therapy of anemia, which, although of great value in improving the blood status of pernicious anemia, does not always prevent the development of funicular myelitis. He suggests that this may be because the spinal symptoms have a causal factor different from that of the blood symptoms. He thinks that larger doses of the preparations may be helpful in preventing the spinal complications and advises that always higher doses be given instead of the minimal dose that is just sufficient to maintain a normal blood status. Blood transfusions are valuable in pernicious anemia primarily for bridging the interval before liver therapy can become active. Other forms of anemia in which blood transfusion is of great help are posthemorrhagic anemia, torpid anemia of the secondary type that does not react to iron or arsenic, anemia pseudoleukaemica infantum, and aplastic forms of anemia. The author recommends extirpation of the spleen for the treatment of hemolytic icterus. In severe cases of essential thrombopenia, he found splenectomy effective, and he suggests that it be tried in some cases of aplastic anemia. Reduced iron or ferrous chloride should be employed in iron therapy because tests indicate that only bivalent iron is absorbed by the organism. Arsenic, formerly widely used in pernicious anemia, is now employed mainly in leukemic disorders, and particularly in those complicated by secondary anemia.

Treatment of Poisoning by Heavy Metals.—Hegler differentiates between the acute and the chronic forms of lead poisoning. In the acute form, the aim is a rapid combination and a harmless storage of the poison in the depots, particularly in the liver and the bone marrow. To attain this end, an alkaline diet and administration of large quantities of resorbable calcium preparations have been recommended. Lead colic is treated with calcium chloride or by slow intravenous injection of from 8 to 10 cc. of a 10 per cent solution of calcium bromide. The spastic constipation may be treated with atropine or with a mixture of atropine and papaverine. The salines, such as carlsbad salt or epsom salt, are generally the best purgatives. Sodium thiosulphate is helpful in the treatment of acute and subacute lead poisoning. In mild cases it is advisable to begin with the intravenous injection of 0.6 Gm. of sodium thiosulphate dissolved in from 10 to 20 cc. of distilled water. This dose may be increased gradually to 1 Gm. In severe cases the initial dose may be 1 Gm. The injections have to be continued for about a week. They exert a favorable influence not only on the lead colic but also on the blood pressure, the hemoglobin content and the general condition. In chronic lead poisoning the aim is elimination of the lead, but care must be taken that the mobilized lead stream does not become strong enough to have an injurious effect. Medication with potassium iodide is helpful and, instead of an alkaline diet, which in acute poisoning aids in carrying the lead into the depots, an acid diet deficient in calcium should be given in chronic lead poisoning. For the treatment of lead paralysis, elimination of the lead is essential, but the galvanic current, massage and injections of strychnine are also advisable. In acute mercury poisoning by mouth the poison should be removed by gastric irrigation and by combination with animal charcoal. Then attention should be given to the kidneys, for their impairment may result in anuria. The author recommends daily intravenous injections of from 20 to 40 cc. of a 33 per cent solution of dextrose, eventually with the addition of sodium

chloride and sodium bicarbonate in order to prevent acidosis and chloride deficiency. Hot packs and pilocarpine are employed for their sudorific effect. The intravenous administration of sodium thiosulphate should be tried. Decapsulation of the kidney has been abandoned in recent times, but roentgen irradiation has been successfully employed. In chronic mercury poisoning the further intake of the poison should be prevented, and elimination should be promoted by sweat cures. The diet should be strengthening, and narcotics are advisable in severe tremor. In the prevention of brass founders' ague, a disease that develops as the result of inhalation of the dust or the vapors of zinc or of zinc oxide, correct ventilation is of primary importance. In the treatment, sweating is helpful and a warm bath should be taken immediately after work. Acute poisoning by arsenic necessitates irrigation of the stomach and medication with arsenic-combining substances. If severe diarrhea exists, intravenous injection of dextrose solution is advisable. Poisoning with arsenic hydride causes hemolysis. For treatment, the author recommends venesection with subsequent blood transfusions, oxygen inhalation and administration of large amounts of fluids. Chronic poisoning with manganese develops generally as a result of the inhalation of pyrolusite, particularly in pyrolusite mills. Exposure extending over a number of years frequently leads to parkinsonism. Once this condition has developed, only symptomatic treatments can be tried. Deposit of manganese dust in the lungs frequently causes pneumonia.

Hysterical Manifestations.—Bostroem advises against the interchangeable use of the terms "psychogenic" and "hysterical." He points out that the term psychogenic is more inclusive than the term hysterical. Hysteria is characterized by a striving after something. Accordingly, hysterical manifestations should be counteracted by disregarding them as disease indicators. Moreover, their occurrence indicates that the person himself is not convinced of the justification of his demands. If this attitude is taken, the hysterical mechanisms would become not only useless but inexpedient and detrimental for attaining their aim, and thus the symptoms would perhaps disappear in the course of time. However, in estimating hysterical reactions greatest caution is necessary, because the person who produces hysterical symptoms is not necessarily healthy. But once the diagnosis has been established and organic disorders have been excluded, the manifestations should be counteracted in the suggested manner.

Influenza Psychoses.—In the course of the last influenza epidemic, Lewenstein and Schmitz observed thirteen patients with psychic complications, which showed a certain uniformity in that the disturbances of motility predominated. In the majority of patients, the disturbances of motility were of a hyperkinetic and, in a few, of an akinetic character. The hyperkinetic manifestations differed from those of catatonic, manic or paralytic genesis by the predominance of iteration and rhythmization. Lively, expressive and purposeful movements, such as beckoning, threatening, polishing, wiping, gymnastic exercises and marching, were the nucleus of the varied play of movements, which occasionally became distorted by parakinetic alternations and then again became monotonous by iteration. Optic and other sensory impressions caused short-circuit actions and interrupted the motor unrest. Sometimes the motor unrest was accompanied by incoherent talking, and then again they alternated. The facial expression was changeable. In the patients with akinesia, the facial expression, as well as the entire body, was rigid. Induced movements were retained. The reactive movements were slow and jerky, and occasionally movements were begun and not completed. Induced movements were sometimes followed by negativistic muscular spasms. The rare

incoherent oral expressions of these patients generally indicated anxiety. The authors observed no relations between the severity of the somatic manifestations and the psychotic disturbances. The influenza took the usual course, and the psychotic manifestations developed generally between the eighth and tenth days following the onset. In the majority of patients, the fever had subsided on the third or fourth day and high temperatures were never observed during the psychosis, but a catarrh of the respiratory tract and signs of pneumonic foci over the lungs persisted in many instances. Circulatory weakness was manifested by pallor and cyanosis. The slight leukocytosis with considerable deviation to the left and the increased sedimentation speed seemed to indicate pneumonic complications. The cerebrospinal fluid was generally normal, but in some patients there was a slight increase in the pressure, the number of cells and the protein content. Since the majority of the influenza psychoses have not yet terminated, the authors will discuss their outcome at a later date.

Cerebral Complications After Vaccination and After Acute Infectious Disease.—Gins calls attention to the fact that the diagnosis of acute encephalitis is extremely difficult and that therefore erroneous diagnoses cannot be considered rare. Moreover, the diagnosis of encephalitis in connection with smallpox vaccination has been made only in the last ten years. Before this period, although cerebral complications occurred in connection with vaccination, they were not brought into causal relation with it. Spasms, for instance, did occur and some of them ended fatally, but statistics from the years 1910 to 1913 show that fatalities in children as the result of diseases of the nervous system not connected with vaccination are comparatively high and that in comparison to this such fatalities in connection with vaccination are not so high as to justify anxiety. The author stresses that in recent years the cerebral complications of vaccination have been carefully watched for, while the cerebral complications after acute infectious diseases have not been given the same attention. He thinks that a number of the latter may have been listed with the first, and he reports a number of cases with erroneous diagnoses. Moreover, the histologic aspects of postvaccinal and postinfectious encephalitis cannot be differentiated and, although the histologic aspects of epidemic encephalitis differ somewhat from those of postinfectious encephalitis, the author does not think this sufficient reason to reject the etiologic unity of all these forms. On the contrary, he is of the opinion that the postinfectious encephalitis are secondary manifestations of epidemic encephalitis. He bases this opinion on epidemiologic reasons. Following an explanation of the histologic differences, he points out that until 1920 postvaccinal encephalitis was practically unknown, and he considers the spreading of epidemic encephalitis a factor in the greater incidence of acute encephalitis in the course of acute infectious diseases. However, this influence can have been only indirect, because postinfectious encephalitis were not observed at the time of the first occurrence of epidemic encephalitis and they made their appearance only after epidemic encephalitis had already been existent for a number of years. He concludes that epidemic encephalitis took a course similar to that which has been observed in other epidemic diseases: first, a period of typical clinical cases, then a period of atypical, partly abortive forms besides the typical ones, and finally a period of wide dissemination of the virus with only occasional typical cases. Many of the virus carriers have a latent infection and do not develop the clinical symptoms, but a few of those with latent infection are predisposed to the disease, when the normal resistance becomes disturbed. The latter group represents the candidates for the postinfectious or the postvaccinal enceph-

alitis, respectively. As proof for this theory, the author cites the fact that postinfectious and postvaccinal encephalitis are most frequent in countries in which epidemic encephalitis had the highest incidence. He states that encephalitis after vaccination is not as frequent as is believed by some, and he thinks that, since the manifestation involves a predisposition, children subject to spasms should not be vaccinated within a year following the last attack of convulsions.

Spontaneous Hypoglycemia Following Gastric Operations.—Beckermann calls attention to a disturbance in the carbohydrate metabolism of patients who have undergone a gastric operation. These patients develop several times each year, or even each month or week, a syndrome that consists in a sudden feeling of weakness, dizziness, tremor and perspiration, a sensation of heat or cold, apathy, restlessness and sometimes an intense feeling of hunger. These disturbances generally develop after meals with a high carbohydrate content. The symptoms disappear quickly after renewed ingestion of carbohydrate. Sugar tolerance tests on patients who had undergone gastric resection revealed not only unusually low blood sugar values but also the clinical symptoms of hypoglycemia. The author thinks that the causes of this form of hypoglycemia are probably manifold, but a surgically induced anastomosis between stomach and intestine always seems to be a causal factor. Although the individual hypoglycemic attack is best treated by oral administration of sugar, the general diet of these patients should have a restricted carbohydrate content and high fat and protein contents, because a diet with high carbohydrate content causes the attacks.

Differential Diagnosis of Abdominal Symptoms in Influenza.—In the course of an influenza epidemic, Wachsmuth observed abdominal disturbances, which developed at the onset or in the course of influenza and resembled the symptoms of appendicitis. The blood picture of these patients was the same as that of patients who did not present the abdominal symptoms. Leukocytosis was absent, but there was a marked relative lymphocytosis. Control tests on patients suffering from acute appendicitis always revealed the typical hemogram with leukocytosis and polynucleosis. The abdominal symptoms of influenza can be counteracted by regional anesthesia, at least to the extent that they are the result of neuralgia or of muscular impairment. In acute appendicitis, however, regional anesthesia does not produce this result, since the pain conduction of the visceral peritoneum, the splanchnic nerve, or the rami communicantes is not impaired. During influenza, every intervention involves the danger of complications. For this reason all diagnostic aids should be utilized to avoid an unnecessary operation.

So-Called Muscular Tears in Athletes.—Jokl and Guttman describe severe muscular pains frequently occurring in athletes and commonly referred to as "muscular tears." Among the causal factors, the authors stress the nervous component, although physical exertion cannot be entirely disregarded in their pathogenesis because the pains develop suddenly in the course of an unusual exertion. The designation "muscular tear" indicates an actual interruption of continuity in the muscle and, because of this term, the condition has often been identified with the actual rupture or the detachment of a muscle. The difference between "muscular tear" and true interruptions of continuity is the absence of any visible or palpable symptom

indicating an interruption of continuity. Moreover, actual rupture of a muscle causes such severe symptoms that an operative intervention is required, whereas the so-called muscular tear generally yields to conservative measures. Some observers are inclined to assume only a difference in degree between these conditions, but the author thinks that an essential difference exists. A report of five clinical histories of persons with "muscular tears" reveals the absence of symptoms indicating an interruption of continuity and the symmetrical character of the disturbance. The author thinks that the symmetry of the manifestation, that is, the contralateral development of the symptom, is additional evidence for the predominance of the nervous component in the development of the "muscular tears."

Epiphyseolysis and Luxation of Hip Joint in Nurslings.—Kleine asserts that, beginning with the second half year of life, luxations of the hip joint show in the roentgenogram a hypoplasia of the center of ossification in the head of the femur and of the entire proximal portion of the shaft of the femur. In epiphyseolysis (subcapital fracture) resulting from obstetric injury, however, roentgenoscopy reveals temporarily on the side of the fracture a hyperplasia of the center of ossification in the head of the femur and, in general, an acceleration of the growth process in all epiphyseal nuclei that are near the fracture. The same acceleration of the epiphyseal growth can be observed also in other fractures near the epiphysis occurring during infancy.

Noctalbuminuria.—Fanconi relates the clinical history of a boy who, between the ages of 10 and 17, had frequent attacks of albuminuria (up to 10 per cent), cylindruria and increased blood pressure. The author based the diagnosis, functional albuminuria, on the following factors: (1) the complete absence of general disturbances, particularly the absence of edemas, headaches and changes in the fundus oculi; (2) the absence of blood elements in the urine; (3) the great changes in the urine, for while the morning urine (as a rule highly concentrated) contained large amounts of albumin and casts, the specimens taken later, contained no pathologic elements whatever (noctalbuminuria); (4) the character of the eliminated albumin, for an acetic acid body, precipitable by cold and characteristic for orthostatic albuminuria, predominated; this body is only rarely found in nephritic albuminuria; (5) the outcome of the concentration and water tests; (6) the normal blood chemistry (rest nitrogen at upper limit of normality); (7) the greatly retarded sedimentation speed of the erythrocytes, which occasionally occurs in orthostatic albuminuria, whereas true nephritis is characterized by a considerable acceleration of the sedimentation speed; (8) the result of the treatment; the patient has been healthy for the last four years. The author shows that the reported case cannot be classified with the orthostatic type or with the form resulting from stasis, but that it is an exsiccation albuminuria.

Echinococcosis of Kidney.—Blum describes the history of a man, aged 48, referred to him on account of a tumor of the left kidney. The first cystoscopic examination revealed the etiology of the tumor, for an iridescent, serous cyst, the size of a date, was seen to issue from the dilated orifice of the left ureter, and pressure on the enlargement of the left kidney resulted in acceleration of the expulsion of the cyst. Anamnesis revealed the intermittent discharge of cysts with the urine, dating back twenty years. The left kidney was extirpated and the patient recovered. The author points out that echinococcosis of the urinary organs is comparatively rare but that echinococcosis of the bladder has shown an increase in recent years. In some districts and countries it has become endemic, owing to the infestation of a large percentage of dogs, sheep, hogs and cattle. In order to prevent further spreading of the condition, the population should be warned to be careful about contact with dogs, and particularly about consuming uncooked foods.

Perinephric Abscess with Pyelonephritic Contracted Kidney.—The case history described by Schwarz indicates that the symptomatology of a perinephric abscess is not always as uniform and typical as is generally believed. The diagnosis was extremely difficult, for, whereas the leukocytosis and the acceleration of the sedimentation speed of the erythrocytes indicated an extensive suppurative process, the roentgenogram seemed to suggest the presence of a tumor. Exposure of the right kidney revealed an enormous perinephric abscess. Subsequently, several metastatic abscesses developed, pyuria continued and the right kidney ceased to function entirely. Nephrectomy was now resorted to, but the patient died on the day following this intervention. All metastatic abscesses developed in parts that had been involved in war injuries. The patient could have been saved if the kidney had been extirpated at the first intervention, but the author states that an extension of the operation to the kidney seemed inadvisable in the presence of the enormous abscess cavity. On the other hand, the secondary nephrectomy was the only intervention that gave some hope of saving the patient.

Contrast Shadows with Level Surface in Cystic Kidney.—Hennig and Lechnir demonstrated in the test tube and on the living organism that thorium dioxide contrast medium is flocculated by mixture with urine. In the roentgenologic visualization of cystic kidney this flocculation results in the formation of contrast shadows that have a level surface. The latter are recognizable in roentgen exposure on the standing patient, and they provide a plastic visualization of the cystic kidney. The author considers this demonstration the method of choice in cystic kidney.

Diet in Treatment of Tuberculosis of Urogenital Tract.—Szold found that the Sauerbruch-Herrmannsdorfer-Gerson diet does not cure tuberculosis of the urogenital tract and that it does not improve the renal function, once anatomic changes have developed, but it reduces the number of painful tenesmi and the frequency of micturitions. Moreover, the weight increases and the general condition improves. The author thinks that in inoperable cases of tuberculosis of the urogenital tract the diet is a valuable adjuvant to the other treatments.

Source of Errors in Detecting Calculi.—In the study of eleven case histories of patients with calcification of the abdominal lymph nodes, Lachs observed certain pointers that are helpful in the diagnosis: 1. Calcified retroperitoneal or mesenteric lymph nodes, as the result of their relations to the renal pelvis and more frequently to the ureters, produce changes that impair the function of these organs. 2. The anamnesis of these patients frequently contains statements about inflammatory diseases of other lymph nodes. 3. The pains produced by calcified abdominal lymph nodes adhering to the ureter resemble greatly the pains produced by renal and ureteral calculi: they are usually localized under the costal arch and, as a rule, are unilateral, either continuous or intermittent and of a colic-like character; they may radiate downward and may be accompanied by disturbances

in the evacuation of the bladder. The body temperature is generally increased. 4. The urinary sediment always contains erythrocytes, but an increase in the number of leukocytes is observed only in cases of simultaneous infection of the urinary passages. 5. Cystoscopy reveals no changes in the bladder, except that occasionally the ureteral orifice of the diseased side is reddish and swollen. 6. Usually the ureteral catheter can readily be introduced up into the renal pelvis, except when the ureter is bent or stenosed by a scar. 7. The elimination of indigo carmine is belated and weaker on the diseased side and may be entirely absent in cases with considerable impairment of the kidney. 8. Roentgenoscopy is the main basis for a correct diagnosis of calcified lymph nodes. They appear as dense, roundish shadows with lighter centers and usually in groups, and they have a tendency to change their position. 9. Roentgenoscopy should be done at two levels and while the ureteral catheters are introduced. 10. Adhesion of calcified retroperitoneal lymph nodes to the ureter may cause constriction of the lumen and impede the urinary discharge, leading to hydro-nephrosis or pyonephrosis.

Advance in Lumbar Anesthesia.—Hollenbach states that, since Americans introduced anesthetic mediums lighter than the cerebrospinal fluid, the method of spinal anesthesia has been given far wider application. Results were further improved by the adoption of Kirschner's method of zonal limitation of spinal anesthesia. The patient's body is placed in an oblique axis with the head lowered and the anesthetic dose is administered fractionally with the Kirschner cannula remaining in situ during the entire operation. The spread of anesthesia can thus be definitely controlled during the operation and the involvement of higher centers definitely prevented. In a group of 1,000 operations, most of them of a serious nature, carried out under spinal anesthesia, there was not a single death or an untoward accident. The author concludes that the method of spinal anesthesia is applicable to practically any operation, except in the presence of a disease of the central nervous system, suppuration of or about the vertebrae, and severe trauma or acute hemorrhage, when an immediate operation is imperative.

Alkali in Treatment of Eclampsia.—Hofbauer shows that the changes which can be produced experimentally by means of extract from the posterior lobe of the hypophysis, the symptoms of eclampsia and the presence of posterior pituitary hormones in the blood indicate that eclampsia results from an oversupply of the hormones of the posterior hypophysis, together with an insufficiency of the capillary endothelium and of the hepatic function. He considers the renal symptoms of secondary nature. He calls attention to the antagonism between extracts of the posterior lobe of the hypophysis and alkalis and states that, since an oversupply of the hormones of the posterior hypophysis is a pathogenic factor of eclampsia, alkali therapy seems justified. He shows that, in addition to a limitation of the food intake, alkalis are the principal factor of the so-called Dublin method, which, in some hospitals, has been the standard treat-

ment of eclampsia for a number of years. The essential factors of this method are submammary infusion of 1 liter of a 1 per cent solution of sodium bicarbonate, gastric irrigations with and retention of 100 cc. of the solution at the end of the irrigation, and intestinal irrigation with and retention of from 0.5 to 1 liter of the solution. Although the original idea was to remove hypothetic toxins from the intestinal tract, the author is inclined to believe that the efficacy of these procedures is due to their inactivation of the hypophyseal action. Moreover, the withdrawal of the gastric juice may effect a change in the acid base equilibrium toward alkalinity and a simultaneous reduction in the blood pressure. The author thinks that his clinical experiences with the addition of a 1 per cent solution of sodium bicarbonate to a 20 per cent solution of dextrose for intravenous medication indicate that alkalis effect a change in the reaction milieu which is important in the production and action of the hormones. As soon as the patients waken from unconsciousness and are able to swallow, they are given 2 Gm. of potassium citrate in water every two and one-half hours. For the treatment of preeclampsia, the author likewise recommends alkali therapy, and in pyelitis gravidarum he employs a combination of sodium bicarbonate and sodium citrate. He thinks that sodium citrate has an influence on the peristalsis of the ureter similar to that of caffeine or solution of pituitary. Encouraged by the results of the treatment of pyelitis, the author now gives sodium citrate for prophylactic purposes. After the fifth month of pregnancy, his patients have to take it three times weekly.

Rare Form of Eclampsia.—Rhemann points out that, whereas formerly convulsions were considered the dominating, even the essential, symptom of eclampsia, it is now generally realized that they are only one of many symptoms and that they may even be entirely absent. Many such cases have been reported in the literature. But besides the cases in which the convulsions are absent, there are also some in which the typical convulsions concur with syndromes entirely foreign to the usual aspects of eclampsia. Because diagnostic errors are likely in such cases, the author gives the history of a case observed by him, in which eclampsia manifested itself through a temporary paralysis of the respiratory center and cyanosis, as the result of a nutritional disturbance of the respiratory center. The striated muscles were not involved in the asphyxia. Had the eclampsia presented only this symptom, the diagnosis would have been doubtful. However, the point of attack of the eclamptic poison changed several times. It shifted to the motor centers, and thus the typical eclamptic syndrome became complete. Later it again shifted from the motor centers to the respiratory center.

Castration by Roentgen Rays.—Feldweg maintains that roentgen irradiation is a valuable method in the treatment of menopausal metrorrhagia and myomas. The menopause produced by irradiation differs neither qualitatively nor quantitatively from that developing spontaneously. The age at the time of castration has no influence on the manifestations resulting from the abolishment of functions. The course of the menopause induced by roentgen irradiation is just like the spontaneous menopause primarily determined by the constitution. Asthenic and emaciated women tolerate irradiation amenorrhea well, and women with hyperthyroidism tolerate it still better. However, the symptoms of abolished function in the natural and in the roentgenologically induced menopause are more pronounced in sthenic and pyknic women and women with hypothyroidism; in the latter, especially, caution is necessary with regard to ovarian irradiations. Neurasthenic, psychopathic and mentally unbalanced women are entirely unsuited for castration by roentgen rays. A certain understanding of the significance of the treat-

ment on the part of the patient is a prerequisite for the success of the treatment.

Treatment of Genital Hemorrhages of Ovarian Origin.—Knab thinks that, since the hormone of the corpus luteum has been separated from the follicular hormone and since its action on the uterine mucous membrane and on the ovary has been determined, there is justification in employing it to obtain hemostasis in certain uterine hemorrhages. By counteracting the secretion of the posterior hypophysis, the hormone of the corpus luteum is thought to have a relaxing influence on the uterine musculature, to produce a hypertrophy of the mammary glands and of the uterine mucous membrane, the latter in the form of the premenstrual phase, and to suppress maturation and ovulation of the follicles. The author resorted to treatment with corpus luteum hormone in patients with genital hemorrhages that were apparently of ovarian origin. The author thinks that the nature of these disturbances lies in a persistence of the phase of proliferation of the uterine mucosa resulting from a persistence of the follicle and a deficient formation of the corpus luteum. He describes the clinical histories of six women with irregular and prolonged menstrual bleeding in whom treatment with corpus luteum hormone was tried. The women were given injections of two rabbit units of the hormone several days in succession. The treatment proved effective in five of the women. The author obtained favorable results also in hypermenorrhea and in polymenorrhea of young girls, as indicated in two case reports. In cases of habitual or threatened abortion, in which other than incretory factors could be excluded, the hormone was likewise successfully employed. The author admits that the small material studied by him does not permit generalizing conclusions, but he thinks that further experiments along this line are justified.

Brenner's Tumor and Endometriosis.—Abraham had the opportunity of demonstrating for the first time the coexistence of an ovarian tumor described by Brenner and of endometriosis in the same organism, thus giving support to the theories of Tonkes-de Snoo and of von Behring as to the origin of endometriosis. The observation likewise supports Robert Meyer's hypothesis which links so-called Brenner's tumor with endometriosis. The author believes that Brenner's tumor and endometrioid tumors have their origin in a common layer; namely, the celomic epithelium. The development of each presupposes a local tissue predisposition as well as a general predisposition and certain hormonal influences of constitutional order. The impetus to their development is undoubtedly controlled by ovarian hormones. The endometrioid tissue as well as that of Brenner's tumor display a tendency to functional differentiation without, however, developing the ability of inducing changes of a biologic significance in the organism. Both tumors give evidence of an inherent tendency on the part of celomic epithelium to localized, temporary and anatomically variable differentiation. Both tumors considered from a clinical and histologic point of view are essentially benign.

Duodenal Diverticula: Two Cases. E. Platou.—p. 528.
*Erythema Nodosum and Later Tuberculosis. H. J. Ustvedt and A. S. Johannessen.—p. 532.

Suture of Esophagus After Resection.—In his experiments on cats, using the finest 000 silk suture material treated

with petrolatum, Ingebrigtsen obtained primary healing of the musculature after resection of 5 cm. of the esophagus, corresponding to 8 cm. in man. He finds little difference between the esophagus in the cat and in man and considers it not impossible to perform circular suture of the human esophagus after resection of 7 or 8 centimeters.

Wallenberg's Syndrome.—Benestad's cases were characterized by acute onset of alternate hemianesthesia to pain and temperature, unilateral trigeminal anesthesia, difficulty in swallowing, hoarseness, lateropulsion, vertigo, Horner's ptosis and hemiataxia. Necropsy in the first case, in a woman aged 40, showed stenosis of the mitral orifice and softening of the cerebellum. The second patient, a man aged 64, still under treatment, is being fed through a gastric fistula.

Erythema Nodosum and Later Tuberculosis.—Ustvedt and Johannessen's study of 314 cases of typical erythema nodosum seems to show a considerably higher morbidity and mortality from tuberculosis in persons who have had erythema nodosum than in the average population. The danger of tuberculosis appears to be somewhat less after erythema nodosum than after pleuritis. The tuberculosis morbidity and mortality follow closely on the erythema nodosum with a marked maximum morbidity in the first year after erythema nodosum and practically no morbidity after five years, and after the first five years no deaths from tuberculosis. The explosion-like morbidity rapidly following erythema nodosum is regarded as supporting the view that the disorder is a phenomenon of hypersensitivity rather than one of lowered resistance.

*Experimental Investigations on Protective Power of Animal Organism Against *Bacillus Histolyticus*. S. Insulander.—p. 5.

Protective Power of Animal Organism Against *Bacillus Histolyticus*.—Insulander carried out his experiments on various animals, using two strains of *Bacillus histolyticus*. He found that normal serum and the plasma, contain active bactericidal substances against *B. histolyticus*, made up of an activable and an activating substance. After immunization with *B. histolyticus* or its toxin, no increase in the bactericidal power of the immune serum over normal serum is demonstrable, although all other antibodies appear. In these respects *B. histolyticus* resembles a bacterium sensitive to betalysin. Immune serums are, in vivo, no certain protection against a fatal dose of the bacteria. Attempts to demonstrate, in vitro, bactericidal substances in extract of leukocytes, thrombocytes, lymphocytes and histiocytes establish such substances only in the leukocyte extract. Attempts to demonstrate a protective action in vivo in these cells showed that the leukocytes protect against from fifteen to twenty fatal doses of washed bacteria and, on the addition of 0.25 cc. of immune serum, against at least forty fatal doses; the other cell types had no protective action. No protective action of these cells against toxin of *B. histolyticus* was demonstrable.

Liver Function in Normal Pregnant Women.—Germer tabulates the results of liver function tests made in fifty normal women during pregnancy. The blood content of quinine-resistant lipases began to increase steadily in the sixth or seventh month, all cases showing a positive lipase reaction about four weeks before delivery, with steady reduction in the last four weeks and certain positive reaction in barely half the cases on delivery and normal lipase content in the blood in all cases at the end of the puerperium. The urobilinogen content in the serum, contrary to the icterus index, presented fairly regular variations agreeing with the changes in lipase content. The result of Hay's test and of the urobilinogen test in the urine agreed closely and were also in agreement with the lipase test.

THE HYPOPHYSECTOMY TYPE OF OBESITY TREATED WITHOUT GLANDULAR MEDICATION

JOSEPHINE HEMENWAY KENYON, M.D.
NEW YORK

An unusual method of treating obesity was described in 1929 by Dr. Evans and Dr. Strang of Pittsburgh.¹ Their further reports² stimulated my interest.

From December, 1931, to March, 1933, fifty overweight patients came under my supervision in private practice and were given a modification of the high protein diet. These patients were chosen because they presented the typical distribution of fat pads, commonly ascribed to hypophysectomy—girdle weight, pads on the upper arms, fat folds across the middle of the back, over the iliac crests, in the supratrochanteric regions and above the knee on the inner side of the thigh. The fat on the abdomen varied from the single or double roll of fat to the overhanging apron. There were ten patients with the very thick lower leg, of the "piano" leg type.

All but six children had dieted previously but had regained their weight in the same areas. Sixteen had been given thyroid and pituitary with no permanent improvement in the obesity. Of the fifty, thirty-six showed mild signs of possible hypothyroidism. The basal metabolic tests of these thirty-six patients were as follows: Eight were below —15 (the lowest —31); twenty-two were between 0 and —4; six were from +1 to +14. These results were calculated on the actual weight of the patient at the time of the test. Seven of the thirty-six patients had been previously given thyroid by other physicians and had taken from one-half grain to 2 grains (0.03 to 0.13 Gm.) daily for years. Their basal metabolic tests at the onset of dieting were 1, 1, —9, —10, —10, —12 and —16. On their thyroid dosage they had not lost in weight; therefore, it was thought a fairer test to allow them to continue with this during the dieting period. With the exception of these seven patients, no glandular therapy was used.

The treatment was preceded by a careful medical examination, urine analysis, blood count and, when indicated, blood sugar or other necessary blood chemistry. The ideal weight was arrived at in two ways: first by finding the weight at which the patient had been

most comfortable and, by comparing this with the various weight tables for height, finally arriving at what would seem to be a wise and safe weight figure; this was called the estimated weight. Since October, 1932, the "Willoughby" method³ of computing the optimal weight has been used to check this estimated weight. The two have not varied more than 5 pounds (2.3 Kg.) and often are within a pound or two.

According to the suggested high protein diet of Evans and Strang,^{2b} 1 Gm. of protein was allowed for each kilogram of the estimated weight. The diet was built around this. It allowed three protein portions daily, two 5 per cent vegetable portions, four 10 per cent fruit portions, with skimmed milk used for the calcium content, and extra vitamin A, D and B added. The diet was thus high vitamin, high protein, high mineral salts. No sugar, butter or bread was used.

Figure 1 shows a typical patient before commencing the diet and after a loss of 74 pounds (33.6 Kg.), which she achieved in eight months. Her diet was based on an estimated weight of 155 pounds (70.3 Kg.). The detail of her diet was as follows:

Breakfast.—One portion of fruit; one egg and the white of a second egg (optional: clear coffee or tea, bread substitute and sugar substitute).

Luncheon.—Three ounces of lean meat, fish or fowl; or a small helping of meat, fish or fowl or pot cheese and 1 glass of buttermilk or skimmed milk; or a large helping of pot cheese; one cup (one-half pint) of 5 per cent vegetables; one portion of fruit (optional: lettuce with special dressing and bread substitute).

Mid-afternoon (optional).—One cup of clear (strained) vegetable soup, or one teaspoonful of vegex in one cup of hot water; or tea or coffee with substitute sugar and two substitute cakes.

Dinner.—Three ounces of lean meat, fish or fowl; one cup of 5 per cent vegetables; one portion of fruit (optional: tomato juice or clear soup and bread substitute).

9:30, P. M.—One half cup of orange juice; one to two tablespoonfuls of Bemax or Embo; or one yeast cake or other vitamin B concentrate.

Also: Haliver oil (plain), one capsule three times a day, and one and a half glasses of well skimmed milk at any time during the day (for this patient). (At least one glass of skimmed milk was allowed each patient.)

The portions of fruit were one small orange, one half cup orange juice, one half of a large apple, one medium sized apple or one baked apple, two medium peaches, one small pear, one half of a grapefruit, three quarters of a cup of diced fresh pineapple, one cup of strawberries, one cup of blackberries, two thirds of a cup of black raspberries, seven eighths of a cup of red raspberries, or one half of a cantaloupe 4 inches in diameter.

The bread substitutes were Heudebert bread sticks or breakfast biscuits, Charasse breads, and cellulbran and cellubiscuits.

3. Shelton, E. K.: Optimal Weight Estimation, *Endocrinology* 16: 492-505 (Sept.-Oct.) 1932.

Read before the meeting of the Women's Medical Society of New York State, April 4, 1933.

1. Evans, F. A., and Strang, J. M.: A Departure from the Usual Methods of Treating Obesity, *Am. J. M. Sc.* 177: 339 (March) 1929.

2. (a) Strang, J. M.; McCluggage, H. B., and Evans, F. A.: Further Studies in the Dietary Correction of Obesity, *Am. J. M. Sc.* 179: 687 (May) 1930. (b) Evans, F. A., and Strang, J. M.: The Treatment of Obesity with Low Calorie Diets, *J. A. M. A.* 97: 1063-1068 (Oct. 10) 1931.

The sugar substitutes were Sucre de Sante, Lister Sugar (in a shaker), Lister Sugar Free Sweets and Heyden's Crystallose.

The cake substitute was Charasse Petit Beurre Lucullus.

The salad dressing was Dianaise or home made French or mayonnaise dressing containing mineral oil.

The fifty patients were divided into three groups according to their initial weight.

Fig. 1.—A, July 6, 1932, the patient weighed 228 pounds (103.4 Kg.). B, Feb. 8, 1933, she weighed 163½ pounds (74.2 Kg.); on March 22, she had lost to 154½ pounds (70.1 Kg.). This patient demonstrated to the audience various exercises supervised by Miss Dorothy Nye, which have helped increase the tone of her muscles. Ten of the fifty patients exercised under supervision during the reduction period. It is not thought that, beyond a certain point, the exercises materially helped in the weight loss, but the patients felt in general that it improved muscle tone and kept them in good condition.

Group 1. Eighteen were below 160 pounds (72.6 Kg.); age range from 10 years to 52 years; weight range from 95 pounds to 157 pounds (43.1 to 71.2 Kg.). They dieted an average of nine weeks, lost an average of 11.6 pounds (5.2 Kg.); that is, at the rate of 1.27 pounds (575 Gm.) weekly. Each one reduced to her estimated weight.

Group 2. Nineteen were between 160 and 190 pounds (72.6 to 86.2 Kg.); age range from 21 to 56 years; weight range from 160 to 185 pounds (72.6 to 83.9 Kg.). The average showed a loss of 16.8 pounds (7.5 Kg.) in eleven weeks, a rate of 1.5 pounds (680 Gm.) a week.

Group 3. Thirteen patients were above 190 pounds (86.2 Kg.); age range from 17 to 67 years; weight range from 193 to 268 pounds (87.5 to 121.5 Kg.). The total weight of these thirteen patients was 2,800 pounds. The average patient of this group was 36 years old. She weighed 215 pounds (97.5 Kg.) at onset, dieted sixteen weeks, and then weighed 185 pounds (83.9 Kg.)—an average loss of 1.9 pounds (862 Gm.) a week.

The weight chart (fig. 2) shows in dotted line these three groups and their weight loss curve; also the actual weight curve of four individual patients. When a weight line shows a stationary or upward curve, there

was a lapse from the diet. These patients were all girls and women who continued their work, attending school or were active in household duties. Therefore, we had no way of controlling measured feeding, as under a hospital routine, and unless they had cooperated no measurable results would have been possible.

It was difficult for some of these patients to learn to eat all that was advised. Breakfast, especially, was a larger meal than they were accustomed to. Previously they had often tried to starve for days or to live on one meal a day. This they were not allowed to do. Gradually they learned to take all that was offered, since they found that their weight reduction depended on their eating the entire amount.

Dr. Evans mentions a possibility of a temporary stationary weight—a water-bound condition. This I found in only one patient. Also there was one patient, at the beginning of the work, who showed mild acidosis for twelve hours.

Diets of various sorts have been advocated for many years. The advantage of this type of high protein, high vitamin, high mineral salt diet is that the patients feel satisfied; they lose only in the fat pad areas; they literally live on their own fat and thereby balance their diet. When their optimal weight is reached, they can return gradually to an unrestricted diet and *not* regain. It is this last point that deserves emphasis. Of the fifty patients, seventeen are reducing to still further levels, believing that their looks will be improved. They feel so well on the diet that they wish to continue. Thirty-three have attained their desired estimated weight and have been on an unrestricted diet. Not one has gained more than 5 pounds (2.3 Kg.); fourteen have lost further in weight, and seven have just held their weight.

All the patients were taken off the diet slowly. The first week unrestricted amounts of vegetables were allowed, and beets, carrots and peas were added, cooked without butter. In the second week they were given unlimited fruits, except bananas, and a baked potato was added once a week. In the third week one slice of bread and one butter pat daily were permitted. During the fourth week there was advised a gradual return to whatever was most desired, which was usually one simple dessert daily. As butter was added, haliver oil was decreased and then omitted. By the fifth or sixth week the patient was taking an unrestricted diet. By this I do not mean that the patients returned to their previous eating of carbohydrates and fats, which most of them formerly craved, or of nibbling between meals. They no longer demanded, for example, double sweet desserts. In fact, in many instances, the craving for sweets disappeared. What happened in each case was a dietary reeducation. Apparently they had learned their lesson. They realized that their fat

Fig. 2.—Weight chart. 1, average loss of group 1; 11, average loss of group 2; 111, average loss of group 3. A, B, C and D indicate weight curves of individual patients. One square in the vertical position equals 2 pounds (909 Gm.); one square in the horizontal position equals 2 weeks.

pads had come from overeating. They are determined never again to appear in such an unfavorable light, nor to be handicapped, as before, by excessive fat.

Of necessity, some patients had to eat at restaurants and cafeterias. Their weight reduction was slower, because they could not obtain food completely without butter and added sugar.

This prescribed diet satisfied appetite. The patients felt better on it. They were more active. The disappearance of shortness of breath was one of the first results noted. There was no premenstrual stationary weight, as is often noted in other reduction treatments.

Four patient had migraine headaches. The sella was described by the roentgenologist in each case as:

1. Average size. This patient was cured of headache after dieting.
2. Average size, but bridged and closed in. Headaches improved.
3. Large sella—14 mm. Headaches improved. (This patient is still under supervision and the size will be checked at intervals.)
4. Small sella—8 mm. Headaches cured. In five other patients, roentgenograms of the skull were taken because of obvious dyspituitary signs. These showed one medium sized sella, one medium sized sella bridged and closed in, two small sized sellae bridged and closed in, and one large sized sella bridged and closed in.

It is interesting that, of the nine, five showed bridging and were described by the roentgenologist as "closed in," but the number is too small from which to draw conclusions.

One girl, aged 17 years, had a blood sugar of 133. and had recurring boils. On the reducing diet, after eleven weeks, she was in better health than she had been for years, with a normal blood sugar and no further infections.

Menstrual difficulties were not prominent in this group of fifty patients. One had amenorrhea with no change after dieting; two with long skips between periods returned to normal after dieting; four with profuse flow at periods returned to normal after dieting; two with irregular flow, profuse at periods and between periods, returned to normal after dieting; fourteen were in the menopause. One patient who had previously been unable to conceive became pregnant when she reached her optimal weight. Her baby, entirely breast fed, is now 5 months old. The patient did not regain her hypopituitary fat pads during the pregnancy nor through the subsequent lactation period.

Contraindications to the use of this high protein diet were considered to be any acute illness, gastric or duodenal ulcer, acute or chronic arthritis with pain in the joints, and nephritis. It is questionable whether a neurotic patient would hold to the diet, or whether it would be wise to attempt it. Essential hypertension is not a contraindication. Nine of the fifty patients had a definitely high blood pressure, and all were reduced to a fair or average systolic and diastolic pressure.

SUMMARY

This study was made for the purpose of determining whether a typical hypopituitary type of obesity could be successfully treated by a carefully worked out high protein diet. The diet was regarded as a treatment for obesity only and not intended to supplant endocrine therapy when indicated for other symptoms. The high protein, high vitamin diet is not advised for use by the layman but should be strictly supervised by physicians

for those patients who, on careful examination, are found free from any acute or certain chronic diseases.

The fifty patients treated showed a steady reduction to their estimated or optimal weight; the fat pads disappeared; the skin contracted, leaving no flabby folds; they held their weight loss on an unrestricted diet for periods varying from five months to more than one year; their general health improved; their blood counts and urinalyses remained normal; headaches were lessened and menstrual disturbances cleared up. There were no untoward symptoms.

Other patients not included in this series are at present on the same supervised diet and show the expected steady rate of loss in weight. The method warrants the physician's consideration and the results justify his enthusiasm.

HYPERINSULINISM

ITS SURGICAL TREATMENT

E. STARR JUDD, M.D.
ROCHESTER, MINN.

FRANK N. ALLAN, M.D.
BOSTON

AND
EDWARD H. RYNEARSON, M.D.
ROCHESTER, MINN.

Hyperinsulinism is the term suggested by Harris¹ in 1924 in explanation of spontaneous hypoglycemia. If there is insufficient insulin, hyperglycemia and diabetes mellitus develop; if insulin is excessive, hypoglycemia develops, with the characteristic symptoms seen after an overdose of insulin. The patient gives a history which in itself points to hypoglycemia; briefly, the history is some variant of the simple fact that when he becomes hungry he has trouble, and when he eats he is quickly relieved. The description of how he feels on these occasions varies from the mere sensation of weakness to attacks of unconsciousness and convulsions. The symptoms all occur when the blood sugar is low and disappear when it is restored to normal, although the complete return to normalcy may be delayed if the reaction has been especially severe. The patient may find that by eating frequently he can prevent the attacks, and as he gives his history he may be nibbling candy or cookies. He may also report the necessity of setting an alarm clock to awaken him at perhaps 2 a. m. that he may eat, and thus prevent an attack in his sleep. Heavy work often produces an attack. Before he consults a physician, his friends may have commented on the fact that he acts peculiarly between meals. If he has had severe symptoms he undoubtedly has been considered drunk. If he has had convulsions he has been called an epileptic.

This type of history is pathognomonic for hypoglycemia. If the patient is seen in an attack, the fact that the condition is identical with that of an insulin reaction substantiates the diagnosis. If he is examined at other times, nothing abnormal will be found, although some patients are obese as the result of the frequent ingestion of food high in carbohydrates.

The laboratory test of blood sugar is needed for confirmation. The blood sugar is low if the test is made

when the symptoms are present; if the blood is taken between the attacks, however, it may be normal. Early in the course of the disease, it may be necessary for the patient to abstain from food and take exercise in order to elicit the symptoms. It may be best, too, to test the blood late in the morning or afternoon. In such case the history is of great importance, for otherwise the change in blood sugar may be overlooked. The intensity of symptoms does not always correspond with the level of the blood sugar. As a rule, symptoms appear when the value for sugar falls below 70 mg. in each 100 cc. of whole blood (method of Folin) and in some cases lack of consciousness occurs when the value is 60 mg. In other cases it may fall to 35 mg. before symptoms appear.

A definite pathologic basis for hypoglycemia due to hyperinsulinism was first demonstrated through the study of a case at the Mayo Clinic in 1926, and reported by Wilder, Allan, Power and Robertson.² In this case, W. J. Mayo found at operation a carcinoma of the pancreas from which Power was able to isolate insulin. Since then, many other cases have been reported; a recent review of these by Wilder³ includes reports of twenty-nine cases in which there was an opportunity to examine the pancreas either at operation or at necropsy. Tumors were found in fifteen of these, two of which were carcinomas with metastasis; hypertrophy of the islands of Langerhans was noted in five, and islands of normal appearance were found in nine. In the literature were twenty-nine further reports of about sixty-five other cases, with symptoms of hypoglycemia, in which the diagnosis rested on clinical observation alone. Since this paper was presented other reports have been published and the number is rapidly growing. The article by Graham and Womack⁴ considers in detail the pathologic observations made in their cases.

When symptoms of hypoglycemia are mild, they can readily be overcome by eating between meals or at any time when the symptoms appear. When there is a strong tendency to hypoglycemia, however, mental confusion, coma, convulsions and other severe symptoms develop, even when care is taken to use sugar at short intervals. There is, therefore, complete disability and constant danger of loss of life. Under such circumstances, radical measures must be undertaken for diagnosis and treatment. Wilder has considered the different conditions which may produce spontaneous hypoglycemia, and also the differential diagnosis.

It is our purpose here to report the results of operation on eight patients at the Mayo Clinic. Three of the cases have been described fully (cases 1, 2 and 3), and four have been described briefly in former publications⁵ (cases 4, 5, 6 and 7). We shall, therefore, summarize the entire group and report on subsequent progress.

ABSTRACTS OF CASES

CASE 1.—A physician, aged 40, had had symptoms of hyperinsulinism for almost two years. The condition became so serious that coma and convulsions occurred unless sugar or

food was given every hour, day and night. Operation by W. J. Mayo, Dec. 4, 1926, revealed carcinoma of the islands of Langerhans with metastatic lesions in the liver. Nothing could be done, and the patient died, Jan. 3, 1927.

CASE 2.—A farmer, aged 52, came to the clinic in August, 1928, because of spontaneous hypoglycemia which had caused symptoms intermittently for more than two years. Loss of consciousness with convulsions was a frequent occurrence. The patient was obliged to take food every two or three hours, day and night, and he was unable to work, since slight exertion precipitated severe symptoms. Operation was performed, September 12, by Judd. The pancreas appeared normal, but a portion of it weighing 14 Gm. was removed. Microscopic examination did not reveal any abnormality. The tendency to hypoglycemia disappeared for two weeks; then the value for the blood sugar became subnormal in the morning, falling to approximately 60 mg. in each 100 cc. However, the patient improved clinically, for if he received three meals each day he was free from symptoms, and he no longer needed to take food between meals or at night.

Reports received from him at intervals indicated that this improvement was maintained for almost a year when hypoglycemic symptoms reappeared, at first rarely, then gradually occurring more frequently until it became necessary to resume taking food between meals and once or twice at night. Later the hypoglycemic tendency increased further and at the last report the man was unable to go without food for more than two and a half hours. He was eating a large amount, using milk and sugar between meals and at night so that his weight had increased from 155 to 220 pounds (70.3 to 99.7 Kg.). He considers that his condition is now somewhat worse than it was at the time of operation.

CASE 3.—A man, aged 47, seen Oct. 2, 1928, had had symptoms of hypoglycemia for four years. Although he ate regularly between meals and at night, loss of consciousness occurred frequently. Operation was performed by Judd, Jan. 2, 1929. The pancreas appeared to be normal, and a portion of the tail, weighing 8 Gm., was removed. Pathologic examination did not disclose abnormalities. The hypoglycemic tendency was not apparent for five days. It then became necessary for the patient to eat frequently and regularly to prevent symptoms, and soon afterward his condition became as serious as before. According to a recent report he is obliged to eat four times during the night besides eating between meals. Since he has taken desiccated thyroid gland it seems possible for him to get along with less food, and further gain in weight has been avoided.

CASE 4.—A farmer, aged 50, came to the clinic, May 13, 1931, because of blurring of vision and vertigo, sometimes leading to loss of consciousness. The symptoms began fourteen months before admission with attacks late in the afternoon before the evening meal, in which he became weak and unsteady. He learned that he could prevent these attacks by eating, but sometimes the symptoms came very suddenly and if he could not eat at once he became unconscious. On one occasion he was unconscious for eighteen hours, and recovery was spontaneous. Diabetes was suspected on one occasion because sugar was found in the urine, probably following the ingestion of a large amount of carbohydrate food.

On examination at the clinic, the value for the fasting blood sugar was found to be as low as 40 mg. A diagnosis of hyperinsulinism was made and an abdominal exploration was performed by Judd, May 25. The pancreas appeared normal except for an area in the tail which was thought to be a small adenoma, but when this part was removed the microscopic examination did not show any abnormality. The tissue resected weighed approximately 5 Gm.

The value for the blood sugar was normal on the day of the operation and on the following day, but on the third day it was 60 mg. It became necessary for the patient to take food regularly to prevent hypoglycemic attacks; mild symptoms appeared a few times. On his dismissal from the hospital his condition was better than before operation, since the symptoms did not occur if food was taken on retiring and immediately on arising. The improvement was maintained for many months, but previous symptoms then returned. He was obliged to take food

S., and Allan, F. N.: Résection du pancréas pour hyperinsulinisme. *Arch. franco-belges de chir.* 33: 281-291 (April) 1932.

between meals and at night and was unable to work because exertion caused dizziness and mental confusion, which occurred frequently and were more difficult to relieve than before. The patient returned to the clinic in April, 1933, and requested further exploration. Judd was again unable to find evidence of a gross lesion. Further resection was technically impossible, but a portion of the pancreas was freed and clamped and allowed to slough away through a drainage tube. Whether improvement will result cannot yet be determined, but in view of experience in similar cases improvement is not expected.

CASE 5.—A man, aged 42, came to the clinic, July 24, 1931, because of spells of stupor which had occurred several times during the previous year. The first indications of trouble were diplopia and blurred vision, always present in the afternoon and disappearing after food had been taken. On other occasions he was in a dazed condition and would do things automatically but without memory of them. On six occasions he lost consciousness completely. His behavior was so peculiar that a diagnosis of hysteria had been made.

The diagnosis of spontaneous hypoglycemia was verified by the test of blood sugar, which, on one occasion, was found to be 20 mg. The result of a general physical examination was negative.

Operation was performed by Judd, August 7, 1931. The pancreas was about half the usual size and showed evidence of chronic inflammation. The capsule of the pancreas was stripped; tissue was not removed. On the afternoon of the operation the blood sugar was 60 mg. and on subsequent tests it continued to be slightly subnormal. The patient was advised to take food between meals and at night in addition to the regular three meals. A recent report indicates that on this regimen he is working daily and without great inconvenience, but he is gaining weight.

CASE 6.—A laborer, aged 45, came to the clinic, Sept. 17, 1931, because of attacks of weakness which had occurred at intervals for four years. The trouble began while he was at work. He became weak and confused, and because he behaved as if he were intoxicated he was discharged from his work. He sometimes had severe attacks in which he became completely unconscious and had convulsions. In one of these he remained in a stupor for sixteen hours and in another for twenty-five hours. He discovered that if he took milk the attacks could be prevented. The day he registered at the clinic he was seen in a restless sleep in which he moved about, and his face and thumbs twitched; he was sweating profusely. Orange juice with sugar was put in his mouth, and gradually he regained consciousness.

The value for the blood sugar was subnormal on many occasions; sometimes it was 40 mg. when the patient seemed normal, but, if it dropped to 30 mg., he became stuporous. Ingestion of food caused a rise in the value for sugar and relief of symptoms. Injection of epinephrine and solution of pituitary caused a slight elevation of blood sugar and retarded slightly the subsequent fall. The general physical examination was essentially negative except for obesity.

Operation was performed by Judd, September 25. A cystic tumor, measuring about 3 cm. in diameter, was found in the body of the pancreas and was excised. The tumor was composed of cells resembling those of the islands of Langerhans with evidence of malignancy. Before the operation the value for the blood sugar was 40 mg.; two hours afterward it was 160 mg., and four hours later it was 190 mg. For the next three days the blood sugar varied between 140 and 160 mg., and from this time on it was never subnormal.

Convalescence from the operation was delayed because of pneumonia and a pancreatic fistula which was present for more than nine months. Recently, the patient reported complete relief from all preoperative symptoms.

CASE 7.—A man, aged 32, who had had spells of weakness and mental confusion at intervals for a year came to the clinic, Aug. 4, 1931. Hypoglycemia had been discovered soon after the onset of the trouble and the patient was advised to take sugar twice in each interval between meals and occasionally during the night. If he failed to take enough sugar, or if he undertook any unusual exertion, hypoglycemic symptoms appeared. Early in the course of the disease he

recognize the prodromal symptoms without difficulty, but later he often failed to notice that anything was wrong until he became helpless and was unable to work.

The value for the blood sugar was usually below 60 mg. when symptoms were present, but on one occasion the blood sugar was 40 mg.; the patient was then apparently normal. There was also the history of gastric distress and roentgen examination disclosed duodenal ulcer and extensive polyposis of the stomach. The general physical examination did not reveal abnormalities.

Operation was performed by Judd in October. Two tumors were found in the pancreas; one about 1.5 cm. in diameter was embedded in the anterior surface of the pancreas at the junction of the body and the tail, and the other on the upper border of the pancreas, 2.5 cm. above the first tumor, was attached to a lymph node about 2 cm. in diameter. On pathologic examination these were found to be tumors of the islands of Langerhans with evidence of malignancy.

The convalescence from the operation was satisfactory and the patient was entirely free from hypoglycemic symptoms. The blood sugar was normal during the first three weeks, but later it was sometimes subnormal, ranging from 50 mg. to 80 mg. in the morning before breakfast. Yet the response to the dextrose tolerance test resembled that of a patient with mild diabetes. The possibility that there might be other tumors buried in the pancreas and that there might be metastatic lesions was considered, and a course of roentgen treatment was given as a safeguard.

The patient reports that he has had good health since the operation. He has been entirely free from hypoglycemic symptoms even when he deliberately went without food.

CASE 8.—A salesman, aged 35, had hypoglycemic symptoms which first became manifest in September, 1926. He was working in a hay field when he became very weak and collapsed. He was helped to his home, where he ate and immediately felt well. He continued to have these attacks between meals, especially if he were engaged in active labor, and always he was relieved by taking food. In April, 1927, he became unconscious and was revived by being forced to drink cocoa. In December, while on a boat to Central America, he was found unconscious in his cabin; the attendants thought him drunk and left him alone. He regained consciousness spontaneously after six hours, ate some apples and felt well. While in Central America he was able to work by eating frequently of bananas. In March, 1928, he was admitted to a fruit company hospital because of convulsions and was told he had epilepsy. Later observation at Stanford Hospital disclosed that the value for the blood sugar was 33 mg., and diagnosis of hyperinsulinism was made. Operation was performed in September, 1928, by Holman. A tumor was not found but a portion of normal pancreas was excised. Subsequently a pancreatic cyst formed which required further surgical intervention; complete healing followed. He was somewhat improved, but by March, 1931, he found it necessary to eat between meals and at 1 a. m. as well. His condition became worse and in October, 1932, he was unconscious for twenty-four hours; he recovered spontaneously.

The patient was admitted to the Mayo Clinic in November, 1932. General physical examination was negative except for slight obesity. Blood sugar determinations made between meals averaged 35 mg. November 25, an operation was performed by Judd, who did not find a definite tumor of the pancreas, but he removed a small nodule. Pathologic examination of the nodule disclosed mild chronic interstitial pancreatitis with marked scarcity of the islands of Langerhans.

The condition since the operation has not markedly changed. Subjectively, the patient is somewhat better, but his blood sugar has continued along its low level except when food is given at frequent intervals.

TECHNIC OF OPERATION

Surgeons have not utilized a standard technic in operating on the pancreas. The prime requisite is that the incision should give adequate exposure. In the

was opened by a long left rectus incision, the usual procedure. The Finneys⁶ advise a T shaped incision; this also should prove satisfactory. The exposure of the pancreas in our cases was made through the gastrohepatic omentum. Certain surgeons make the exposure through the gastrocolic omentum. In resecting the pancreas, the body is grasped with a pair of De Martel intestinal clamps and lifted away from its bed; the surrounding tissues are separated and pushed back, and bleeding is controlled. Holman and Railsback⁷ have suggested that it might be advantageous to remove the spleen with the tail and body of the pancreas, in order to overcome any difficulty in controlling the bleeding. Removal of a tumor has usually been accomplished by dissecting it from surrounding tissue. In the case in which Newton⁸ operated, however, the tail of the pancreas, which contained the tumor, was entirely resected. The cut surface may be closed by suture. In some of our cases clamps were left on the remnant of pancreas in preference, since they might serve as a drain also. A drain of some sort has usually been employed. Newton made the closure without drainage, and the outcome was successful. In some cases, however, a pancreatic fistula has drained for a short time. With one exception, these healed without trouble. In this case, there was drainage for several months before healing was complete.

COMMENT

The results of attempts to treat hyperinsulinism surgically depend on the condition found at operation. If carcinoma of the islands of Langerhans and multiple metastatic nodules are present, nothing can be done, but if a localized tumor of islet tissue is found and removed, the patient will recover completely. When there is no gross change in the pancreas, resection of a part of the gland may give partial or temporary relief, but the prognosis is uncertain. The results thus far have not been encouraging, probably because not enough gland has been removed to influence adequate production of insulin. As Wilder has pointed out: "The situation is analogous to that of the early history of surgery in hyperthyroidism. The results in this new field ought to be as good as those now obtained in hyperthyroidism by thyroidectomy and I predict they will be." The Finneys demonstrated "the feasibility of removal of large portions of the pancreas as a comparatively safe and simple procedure."

Medical treatment has proved unsatisfactory in cases in which there was a strong tendency to hypoglycemia. The palliation of frequent feedings of food high in carbohydrate is efficacious in mild cases, but when the condition is severe even frequent large feedings may fail to prevent symptoms. The gain in weight which results from constant overeating may be a further handicap. Diets high in fat and relatively low in carbohydrate have been employed with varying results. Various drugs and endocrine preparations have been tried in an effort to create resistance to insulin. Desiccated thyroid gland, extract of the posterior lobe of the pituitary gland, and epinephrine have been used particularly because of their antagonistic effect to insulin. Epinephrine may be helpful for emergency use in resuscitation of a patient who has lost conscious-

ness, yet the action is not very strong and is not maintained. Thyroid gland sometimes seems to decrease the amount of food required, but the dosage which can be given does not give adequate relief. Therefore, in serious cases, the aid of the surgeon must be sought. If there is a constant tendency for the value of the blood sugar to fall below 50 mg. and severe symptoms of hypoglycemia develop which keep the patient from working and earning his living, operation is justified. If the condition is severe, there is a strong possibility of the presence of organic disease in the pancreas. The importance of early removal of a malignant or potentially malignant tumor must be considered.

CONCLUSIONS

Hyperinsulinism is a disorder which can be suspected from the history of spontaneous symptoms of hypoglycemia and the demonstration of a low value for blood sugar.

Medical measures frequently fail to give complete or lasting relief, and surgical intervention must then be considered.

Surgical treatment is eminently successful (curative) if a localized islet tumor can be removed from the pancreas. It has failed to give satisfactory results in the absence of tumor, but in such cases more radical resection of the pancreas may be effective.

Surgical treatment is indicated when a patient has hypoglycemia with severe symptoms causing disability. The prospect of cure by operation and the possibility of malignancy are the factors that should influence the decision.

THE NEWER TREATMENT OF STRYCHNINE POISONING

REPORT OF AN UNUSUAL CASE

SAMUEL STALBERG, M.D.

AND

HAROLD S. DAVIDSON, M.D.

ATLANTIC CITY, N. J.

This case is reported for the following reasons: (1) the unusual delay in the appearance of the actual convulsions (forty-nine hours after ingestion of the poison); (2) the unusual length of the period during which these convulsions occurred (five and one-half days); (3) the treatment by intravenous injections of sodium amytal, which in our opinion was the life saving measure; (4) the use of tribrom-ethanol anesthesia, which was supplemental to the sodium amytal, enabling us to use less of the latter than otherwise would have been necessary (this is the first case of strychnine poisoning in man in which tribrom-ethanol was employed); (5) a medicolegal angle involving differential diagnosis between its first stages and acute alcoholism.

HISTORY OF CASE

A woman, aged 30, weighing 105 pounds (48 Kg.), Oct. 9, 1932, at 10:30 a. m., one-half hour after eating a light breakfast, accidentally swallowed approximately $1\frac{3}{4}$ grains (0.11 Gm.) of strychnine in the form of sugar coated pills. In about fifteen minutes, she became nervous and restless and experienced stiffness of the neck and limbs. She was taken to the accident ward of the Atlantic City Hospital at noon, where she was given, by hypodermic administration, one-tenth grain (0.006 Gm.) of apomorphine hydrochloride, which caused vomiting, 20 grains (1.3 Gm.) of tannic acid, 30 grains (2 Gm.) of chloral hydrate, and 20 grains of sodium bromide. The stomach tube was not used. She was discharged two and one-half hours after admission. One of us (S. S.) then first took

6. Finney, J. M. T., and Finney, J. M. T., Jr.: Resection of the Pancreas, *Ann. Surg.* 88: 584-592 (Sept.) 1928.

7. Holman, Emile, and Railsback, O. C.: Partial Pancreatectomy in Chronic Spontaneous Hypoglycemia with a Review of the Cases of Hypoglycemia Surgically Treated, *Surg., Gynec. & Obst.* 61: 591-600, (March) 1933.

8. Newton, F. C.: Personal communication to the authors.

charge of her, at 3 p. m., or five hours after she took the strychnine. She felt sick and low in spirits. Emesis was again induced, a hypodermic of one-fourth grain (0.016 Gm.) of morphine sulphate was given, and she was put to bed in her home. Throughout that evening and the following day and night she had severe pain in the back of the neck and in the back, and there was very frequent clonic jerking of the head laterally. She was given from 5 to 10 grains (0.3 to 0.6 Gm.) doses of chloral hydrate and from 10 to 20 grains (0.6 to 1.5 Gm.) of potassium bromide every three or four hours. Danger of convulsions was deemed past after twenty-four hours from the time of ingestion of the poison had elapsed.

At 11 a. m., October 11, forty-nine hours after taking the pills, a convulsion, the first one, started, which lasted thirty minutes. She was sitting up in bed, the head was retracted and jerked violently; the arms jerked spasmodically and violently; the trunk as a whole was in severe spasm and there was an anxious expression in the face and a feeling of oppression in the chest. Attempts to control this convulsion by inhalation of amyl nitrite and ether on cotton sponges were entirely unavailing. Three hours later, another convulsion, more severe than the first, started. With the patient sitting up in bed, there were violent tetanic spasms of every part of the body, with retraction of the head, opisthotonos, risus sardonius, frothing at the mouth, and anxiety; the patient cried in agony, bitterly complaining that she was choking. The amyl nitrite and ether again were of no value in mitigating the attack. One of us (H. S. D.)¹ then suggested the intravenous use of sodium amytal. After forty-five minutes of the seizure, before it was completely over, the contents of a 7½ grain (0.5 Gm.) ampule of sodium amytal was given intravenously. With the injection of the first drop, the patient fell into a deep sleep and was removed to the hospital. She began to wake up at 1 a. m., October 12, ten hours after the injection. At 5 a. m. the temperature was 101; pulse, 112; respiration rate, 32. At 9:15 a. m., 1:45 p. m. and 2:30, the patient had convulsions lasting, respectively, twenty, ten and five minutes. Oxygen, chloral and bromides were given. At 5:30 another convulsion started, for which chloroform inhalation and artificial respiration were unavailing. Seven and one-half grains of sodium amytal was then given intravenously. At 11 o'clock she was restless in spite of bromides and sodium amytal by mouth and was given another 7½ grains of sodium amytal, intravenously. She was unconscious for five hours and then became restless again. Bromides and sodium amytal by mouth were given. She lapsed into unconsciousness again, and at 6 a. m., October 13, the extremities were cold, the pulse was feeble and there was excessive mucus in the bronchi. A little later she was very weak; there was some difficulty in swallowing, and respiration was of the Cheyne-Stokes type. Coramine and atropine were given hypodermically. At 12:30, 3, 5:45 and 6:20 p. m., she had convulsions lasting, respectively, two, ten, five and ten minutes. At 8:05, she had a severe seizure lasting forty minutes, with risus sardonius and opisthotonos, and complained of inability to see. Following this seizure she slept all night.

October 14, at 8:55 a. m., the patient had a severe convulsion with opisthotonos lasting forty-five minutes. At 10 o'clock, while blood was being withdrawn from a vein, another convulsion started. At the end of one hour of this, 7½ grains of sodium amytal was injected intravenously, with sleep immediately ensuing, and lasting four hours. At 6:30 p. m., the patient was conscious of a rapid pulse and jarring of the entire frame, which went into a convulsion involving the entire body. After fifteen minutes of the spasm, 4 grains (0.26 Gm.) of tribrom-ethanol (175 cc.) in 6 ounces of water was given by rectum. Sleep ensued a minute later and lasted six hours. The use of tribrom-ethanol was suggested by Dr. Harry Subin of the surgical staff.

October 15, at 12:45 a. m., the patient had a convulsion of the entire body with risus sardonius. Tribrom-ethanol was given as before at 1 o'clock, followed by restless sleep of seven hours. At 9 o'clock a convulsion of the entire body started. The patient complained of neck pain and fatigue and begged

to be relieved. After seventy-five minutes of the spasm, 7½ grains of sodium amytal was given by vein. Sleep for seven hours followed. At 7 p. m., with the head and limbs twitching, the patient was exhausted and complained of a "dark curtain over the eyes." Tribrom-ethanol, as before, was given at midnight, with nine hours of restless sleep ensuing. The temperature dropped to 96.4 F., rectal. Nearly all of the convulsions were preceded by a premonitory cry and were accompanied by itching of the scalp and skin, and pain in the neck and chest. Sodium amytal by mouth, chloral and bromides were administered after some of the seizures.

October 16, the head twitched for five minutes in the morning and at 4 p. m. there was twitching of the head and violent thrashing about of the limbs. She was given 5 grains (0.3 Gm.) of chloral and she soon quieted down. This was the last spasm. She was free from symptoms until October 18, when she was discharged from the hospital.

The urine and blood chemistry were normal.

ANALYSIS OF CASE

The amount of strychnine taken by the patient was approximately 1¾ grains (0.11 Gm.). This is slightly above the average fatal dose for an adult, which is 1½ grains (0.09 Gm.). The restlessness, stiffness, neck pain, twitches and convulsions themselves were typical. The altogether atypical and unprecedented feature was the delay in the appearance of the convulsions and the length of the period during which they lasted. The first seizure did not occur until forty-nine hours after the ingestion of the poison; the last one, seven days and eleven hours after the ingestion; the period between the first and last convulsion was five days and eleven hours; the total number of convulsions was seventeen. Nothing like it could be found in the literature. The descriptions in the textbooks and in recorded cases measure the time of appearance of convulsions in minutes or at most a few hours, and the entire duration of the toxic state, both in the fatal cases and in those in which recovery takes place, several hours.

The delayed appearance of the convulsions was probably due in part to the food in the stomach at the time of the taking of the poison, to the fact that it was in the form of sugar coated pills, and to the depressants administered, chloral and bromides. That the latter were totally insufficient to prevent the ultimate appearance of the severe and numerous spasms can be seen from the history of the case.

We are unable to offer any explanation for the unusual length of the period throughout which the convulsions lasted (five and one-half days).

No similar case is recorded. Ornsteen² says that he recently observed at the Philadelphia General Hospital two or three cases of strychnine poisoning that lasted three or four days, with fatal outcome. The data on these cases are, however, as yet unavailable.

With regard to treatment, the patient received five injections of sodium amytal by vein for a total of 35 grains (2.3 Gm.). Four injections of tribrom-ethanol, and, by mouth, 5 capsules of sodium amytal, 2 drachms (7.5 cc.) of chloral hydrate and 1 ounce (30 Gm.) of bromide salts; one-half grain (0.03 Gm.) of morphine and one-tenth grain (0.006 Gm.) of apomorphine hydrochloride. Oxygen, chloroform, ether, amyl nitrite and artificial respiration were tried during the convulsions.

EFFECTS OF THE SODIUM AMYTAL

Narcosis was produced immediately and lasted from six to ten hours. When given while the convulsion was still in progress, the latter ceased at once. The effect

1. To Dr. Davidson, for first suggesting to me (S. S.) the use of sodium amytal intravenously in this case and administering it, to which the patient owes her recovery, entire credit must be given.

2. Ornsteen, A. M.: Personal communication to the authors.

was immediate and complete, and the sleep was deep and free from restlessness.

In our opinion, the sodium amytal injections by vein saved the patient's life. On the other hand, the untoward effects of this barbiturate were also manifest. Thus, the excessive mucus in the bronchi, dysphagia, feeble pulse, cold extremities, and the general appearance of collapse, present on the morning of October 13, were no doubt due to the two injections given the previous evening. Lilly's pamphlet on sodium amytal³ warns of the dangers of its use by the intravenous route and advises such administration only in those cases in which immediate relief is urgent.

TRIBROM-ETHANOL

Four rectal injections of tribrom-ethanol, 4 grains (0.26 Gm.) each, were given. This case was the first in man to be treated with this anesthetic. Sleep after each injection followed in a few minutes and lasted from five to nine hours. The sleep was more restless than after the amytal injections, but there seemed to be no untoward effects. However, convulsions followed the awakenings from tribrom-ethanol much sooner than after those from the sodium amytal.

Sodium amytal by mouth had apparently no effect whatever. The benefit from chloral hydrate and potassium bromide, long used in strychnine poisoning, cannot be exactly evaluated in this case. As stated before, they may have had something to do with the delay in the onset of the convulsions. But once the convulsions started, these drugs had but little appreciable influence either in stopping them or in preventing fresh ones from occurring.

Amyl nitrite, chloroform and ether proved of no value whatever in stopping the convulsions. Artificial respiration during the attacks was entirely futile and meddlesome.

Morphine was also without effect. As it stimulates the motor and reflex functions and depresses the respiratory center, it would tend "to augment rather than allay convulsions."⁴ Used in sufficient quantity to control the convulsions, it is likely to prove fatal.

THE NEWER TREATMENT OF STRYCHNINE POISONING

The chapter on the treatment of strychnine poisoning must be entirely rewritten. The directions for treatment in the latest textbooks are virtually the same as those of a generation back. These are, essentially, the evacuation of the stomach, the giving of a chemical antidote, the administration of chloral and bromides, and, for the convulsions, chloroform, ether, amyl nitrite and artificial respiration. With this treatment the mortality from strychnine poisoning is still above 35 per cent. The profession is no more advanced in the treatment of this condition than the textbooks. It would seem, moreover, that the medical schools are woefully derelict in the teaching of toxicology. Morphine is still used, despite its dangerously synergistic action to strychnine. The intern at the receiving ward of the hospital did not wash the stomach and he discharged the patient after a stay of less than two and one-half hours, as she "showed no symptoms," whereas a thorough knowledge of the potentialities should have prompted him to admit her for close observation. Another intern advised enthusiastically the use of morphine.

The difficulty with chloroform and ether is that they may cause respiratory failure when given in amounts sufficient to control the convulsions. Chloral and the bromides are useful only to a very limited extent.

The barbiturates, especially sodium amytal, intravenously, have opened up a new and hopeful chapter in the treatment of strychnine poisoning. The great usefulness of these drugs consists in the fact that they are anticonvulsant and detoxifying motor depressants, that they can be given intravenously in just sufficient amount to control the convulsions, and that strychnine itself is an antidote to them.

The use of the barbiturates in strychnine poisoning and in other convulsive states was developed by many investigators.⁵

The modern treatment of strychnine poisoning, therefore, consists chiefly and preeminently in the intravenous administration of sodium amytal, either during the premonitory stage or when the convulsion has begun. The dose is $7\frac{1}{2}$ grains (0.5 Gm.). Smaller or larger doses to be used as required and repeated with each convulsion. In severe cases, when repeated injections of the barbiturates are required, they may be supplemented with tribrom-ethanol anesthesia. Giving a chemical antidote, such as tannic acid, and lavage of the stomach are also important. Chloral and bromides may also be given.

To date, eleven cases have been reported of human strychnine poisoning treated successfully with sodium amytal. Our case is the twelfth. Kempf, McCallum and Zervas⁶ reported ten cases and one case treated with pentobarbital. Wheelock⁷ reported one case.

DIFFERENTIAL DIAGNOSIS BETWEEN STRYCHNINE POISONING AND ACUTE ALCOHOLISM

The necessity for a differential diagnosis between strychnine poisoning and acute alcoholism would probably not occur to any one. Yet, a situation developed in this case involving such differentiation. The patient was sitting in an automobile when she swallowed the pills. Soon experiencing the agitation and restlessness which characterize the first effects of strychnine, she drove off. After several minutes, stiffness of the neck and limbs having set in, she crashed into a tree. The police, observing her confused condition, considered her drunk and took her to their police surgeon, to whom they imparted their opinion. The latter, noticing her unsteady gait, without further examination declared her drunk and she was held on a charge of drunken driving. At the hearing before a police judge, after the patient's recovery, the police surgeon, though he was acquainted with the fact of her having swallowed the strychnine before she was brought to him and of her stormy course at the hospital, stuck to his previous opinion, and she was convicted of the charge. Later, on appeal, a higher court discredited this testimony, reversed the police judge's verdict and exonerated her entirely. That there is some similarity in the symptoms of acute alcoholism and the first stages of strychnine poisoning can be seen from the following:

Alcohol.—Alcohol causes a general feeling of well being. Soon there is weakness of muscular movements, particularly noticeable in staggering gait.⁸

Signs of Strychnine Poisoning.—Restlessness and increasing agitation are soon followed by muscular stiffness, accompanied by toddling and unsteadiness in walking.⁹

SUMMARY

The case of strychnine poisoning reported was of unusual duration and intensity. It was treated by intravenous injections of sodium amytal, with supplemental use of tribrom-ethanol anesthesia.

CONCLUSIONS

1. Sodium amytal intravenously is life saving in cases of strychnine poisoning and should be resorted to from the first. It is the ideal drug from a pharmacologic, physiologic and clinical standpoint.

2. Tribrom-ethanol is useful as an adjuvant.

3. More attention should be paid in medical schools to the teaching of toxicology.

VIOSTEROL OF HIGH POTENCY IN
SEASONAL HAY FEVER AND
RELATED CONDITIONS

B. Z. RAPPAPORT, M.D.

AND

C. I. REED, Ph.D.

CHICAGO

Until recently, the literature on the blood calcium and the therapeutic value of calcium in allergic conditions has been replete with contradictions. It is unnecessary in this work to do more than summarize various views. Briefly, there are those who believe that a calcium deficiency is present in allergy, and that calcium is indicated as an adjunct in treatment, and those who find no such deficiency and deny the value of calcium as a therapeutic agent in allergic conditions. Almost all the work since 1928 based on blood chemistry studies made since the development of the Kramer-Tisdall technic for calcium determination supports the latter point of view. Among the more recent workers who also review the literature to date are Cohen and Rudolph¹ and Ramirez.² In studies on a large number of various types of allergic conditions these workers found no calcium deficiency and no improvement or only transitory benefit from the use of calcium in large doses. Crip and McElroy³ in a study of forty-three patients with hay fever, twenty-one with vasomotor rhinitis and two with angioneurotic edema, found no calcium deficiency. The administration of 5 Gm. of calcium three times daily by mouth with and without parathyroid or with and without exposure to ultraviolet rays failed either to relieve the symptoms or to increase the blood calcium in these individuals. The authors explain the temporary beneficial effect of intravenous injections of calcium salts on the basis of its depressant action on the irritability

of all tissue, especially that of the nervous system, as well as its tendency to lessen cell permeability.

The use of viosterol (irradiated ergosterol) or of cod liver oil in allergic conditions has been mentioned casually in the literature since 1930. Its use has been empirical and the dosage small, with no attempt to determine its effect on the blood chemistry. Thus Brown⁴ recommends, in addition to calcium compounds for perennial hay fever, the use of cod liver oil with viosterol 10 D in doses of a teaspoonful of the mixture three times a day.

Jacobsen⁵ reports a rapid disappearance of eczema in four patients who were given viosterol.

Smith⁶ recommends the use of cod liver oil and calcium lactate as a general health measure in the treatment of asthma.

Kitsuta⁷ used cod liver oil and yeast in treating his own hay fever. He reports excellent results from the use of four teaspoonfuls of the oil three times daily.

It is now well established that viosterol produces profound effects on calcium and phosphorus metabolism, the extent and direction of which depend on the dosage, the duration of administration, the diet, the previous state of this process in the subject and probably also the individual reactivity of the subject, which in turn may depend on many factors not yet determined.

In the normal subject, administration of this substance by any route, orally, intravenously or intraperitoneally, produces an increase in the blood calcium concentration. By repeated administration and careful grading of the dose this effect may be maintained over long periods, although work in this laboratory indicates that there may be occasional remissions, not yet clearly understood. In dogs a hypercalcemia of 30 mg. per hundred cubic centimeters has been found that persisted for as much as ten days after the administration was discontinued. In human subjects we have produced a hypercalcemia of 24 mg.

In this laboratory it has been noted occasionally that administration of viosterol to normal subjects, both human beings and dogs, resulted in a lowering of calcium for two or three hours with a rise above normal one or two days later. The extent and duration of this change, together with the observed constancy of decrease of calcium elimination, suggests that the calcium disappearing from the blood must have been deposited in the bones and possibly in the soft tissues.

It appears further that small doses of viosterol result in increased deposition of calcium in the bones and possibly in other tissues, a process that may be reversed after the administration ceases and the body stores of the substance are depleted.

PROCEDURE

Our study was begun during the winter of 1930 with three patients suffering from chronic asthma and two patients with persistent and prolonged urticaria of unknown origin. We had at that time no data on the effectiveness of viosterol when given by mouth. Sterile viosterol in the concentrations of 8,000 X and 10,000 X was used. These concentrations are respectively 80 and 100 times the concentration of the 250 D commercial

preparation. In these five patients it was administered intravenously, in some daily, in others twice a week, in doses of 0.5 cc.—the equivalent of 40 cc. of 250 D when 8,000 X was used and of 50 cc. when 10,000 X was used. In the summer of 1932 our study was extended to include six ragweed sensitive patients with and without asthma complicating their hay fever.

Determinations of plasma calcium, potassium and phosphorus were made on each patient before the vios-

Chart 1.—The effect of viosterol (10,000 X) on the calcium, inorganic phosphorus, potassium and the potassium/calcium ratio in a patient with chronic asthma. A, severe asthma; B, mild asthma; C, no asthmatic symptoms. The star indicates the intravenous injection of 0.5 cc. of viosterol 10,000 X.

terol was administered. A minimum of three control determinations was made on heparinized blood drawn on separate days. In most cases duplicate determinations were made. In some individuals as many as eight control determinations were made to establish the normal variations. After beginning the use of viosterol the patients were seen daily for the observation of symptoms. Blood determinations were made daily on some and twice a week on others. Calcium determinations were made by the Clark-Collip modification⁸ of the Kramer-Tisdall method; phosphorus by that of Fiske and Subbarow,⁹ and potassium by that of Kerr,¹⁰ later replaced by that of Breh and Gaebler.¹¹

VIOSTEROL IN CHRONIC INFECTIOUS ASTHMA

The histories of the three patients studied may be summarized together for the sake of brevity. All had had severe to moderate asthma for six months or longer. A man, aged 60, had the condition for about twenty years. Another man, aged 35, had asthma for four years. The third, a woman, aged 46, had asthma for two years. All were tested by the cutaneous method with all the allergens generally in use and intracutaneously with ninety of the common foods and the inhalant substances. No positive skin reaction was obtained in any of the three patients. The asthma was attributed to chronic sinus infection or chronic bronchitis. Both of these conditions were sufficiently severe in all to consider infection as the likely cause of their symptoms.

The effect of viosterol on these three subjects is illustrated by the record of one of them (chart 1). The similarity of the results in the other two patients renders it unnecessary to include their records in detail.

In a man, aged 35, whose asthma was of four years' duration, the attacks were present with only incomplete

remissions for two years. Feb. 12, 1931, he was admitted to the hospital and placed on a diet containing a definite amount of calcium. Blood chemistry studies were made for eight days before the administration of viosterol. As will be noted in chart 1, a considerable variation in the levels of calcium, potassium and phosphorus was found from day to day during this period. The variation in this individual was, however, greater than in any of the other patients studied. While this degree of fluctuation may be unusual, our observations on the other subjects indicate that such a variation from day to day is not to be considered uncommon in allergic individuals.

March 2, a series of ten intravenous injections of viosterol 10,000 X in 0.5 cc. doses was begun. The detailed results are shown in chart 1.

The other two subjects responded in a similar manner. One was under observation from Dec. 15, 1930, to March 17, 1931, the other from February 26, to March 18, 1931. The first received fourteen intravenous injections of viosterol or a total of 7 cc. of 10,000 X. The blood calcium was increased from the original level of 10.66 mg. per hundred cubic centimeters to 16.0 mg. The third patient received nine injections of 0.5 cc. viosterol 10,000 X. The blood calcium varied between 10.93 and 11.85 mg. per hundred cubic centimeters during the control period. It was raised under the influence of viosterol to a maximum of 15.79 mg. per hundred cubic centimeters. In spite of the marked hypercalcemia produced in all three patients, no definite alleviation of the symptoms occurred in any of them.

THE EFFECT OF VIOSTEROL ON CHRONIC URTICARIA

To avoid erroneous conclusions resulting from spontaneous remissions of urticaria, two patients who had had daily attacks of hives for long periods of time were chosen for this study. Both were tested with foods and contact substances in the same manner as the asthma patients. No positive reactions were obtained.

Chart 2.—The effect of viosterol (10,000 X) on the calcium, inorganic phosphorus, potassium and the potassium/calcium ratio in a patient with chronic urticaria. A, severe urticaria; B, moderately severe urticaria; C, mild urticaria; D, no urticaria. The star indicates the intravenous injection of 0.5 cc. of viosterol 10,000 X.

Both were permitted to remain on a general diet. Chart 2 summarizes the results of the study of the first patient, whose urticaria was of five months' duration. The blood calcium in this patient was 9.86 and 10.20 mg. per hundred cubic centimeters over the three days before viosterol was administered. Five-tenths cubic centimeter of viosterol 10,000 X was given intravenously twice a week from Jan. 17 to Feb. 14, 1931. The patients kept a daily record of their symptoms.

8. Clark, E. P., and Collip, J. B.: *J. Biol. Chem.* **63**: 461 (March) 1925.

9. Fiske, C. Y., and Subbarow, Y.: *J. Biol. Chem.* **66**: 375 (Dec.) 1925.

10. Kerr, S. E.: *J. Biol. Chem.* **67**: 689 (March) 1926.

11. Breh, F., and Gaebler, O. H.: *J. Biol. Chem.* **87**: 81 (May) 1930.

The blood calcium was consistently high with only an occasional fall to the level present before the beginning of the injections. On ten of the twenty-six days during which blood was drawn after beginning the treatment it was 12 mg. per hundred cubic centimeters or higher; on five days, over 13 mg., with a maximum of 15.54 mg. per hundred cubic centimeters. While some improvement occurred in the urticaria, this was not parallel with the calcium level in the blood. The

Chart 3.—The effect of viosterol (10,000 X) on the calcium, inorganic phosphorus, potassium and the potassium/calcium ratio in a patient with seasonal hay fever: 1. 0.5 cc. 10,000 X viosterol by mouth daily. 2. 1.5 cc. 10,000 X viosterol by mouth daily. 3. 2 cc. 10,000 X viosterol by mouth daily. 4. 1 cc. 10,000 X viosterol by mouth daily. O, administration discontinued. A, very mild nasal itching. B, vomited.

improvement was temporary and was consistent with the history of slight spontaneous remissions that had occurred previous to the administration of viosterol. January 28, the first patient began to have daily headaches. February 2, she experienced dizziness and weakness, symptoms subsequently determined to be due to overdosage of viosterol. The symptoms subsided when the injections were omitted for one week. It will be noted in chart 2 that the blood calcium was maintained at a fairly high level for nine days after the injections were discontinued.

The second patient with urticaria had had daily attacks for from four to five years. These were more marked during the premenstrual and menstrual periods. The study began on Jan. 2, 1931, and ended, February 21. She was seen daily. A total of thirty-one blood determinations were made during the fifty-two days of observation. The blood calcium under treatment was raised from 11 mg. per hundred cubic centimeters to a maximum level of 13.7 mg. per hundred cubic centimeters. As in the preceding case, no improvement was observed.

THE EFFECT OF VIOSTEROL ON POLLEN SENSITIVE PATIENTS

This is a preliminary study of the effect of massive doses of viosterol on the calcium metabolism and symptoms of seasonal hay fever and asthma.

Six known ragweed sensitive patients were chosen for this study. We selected intelligent individuals whose symptoms had been severe during previous seasons. Viosterol 10,000 X was taken by all of them in doses to be indicated later, from about July 20 on. No other medication was used either locally or internally. In spite of the definitely beneficial results to be recorded later we hesitate at present to draw any but the most

tentative conclusions from such a small group of patients.

To conserve space, the protocols and charts of two of the patients are given, while the results on the other four are more briefly summarized.

E. S., a girl, aged 15 years, had had autumnal hay fever for many years but no asthma. She had never had any treatment. Blood for control determinations of calcium, potassium and phosphorus was drawn on July 11, 14 and 18, 1932, and thereafter twice a week (chart 3). She began taking 0.5 cc. of viosterol by mouth daily on July 18. On August 8, the dose was increased to 1.5 cc. daily. On August 15 she complained of itching of the nose. The dose was increased to 2 cc. daily. She became nauseated and vomited, August 22. The dose was reduced to 1 cc. daily and the symptoms disappeared. Aside from the complaint on August 15, she had no hay fever symptoms during the entire season. She discontinued taking viosterol on September 24. This is the only one of the six cases for which practically 100 per cent relief of symptoms could be claimed.

One other patient of this group had hay fever uncomplicated by asthma. A man, aged 21, a medical student, had symptoms which were of six years' duration. One season of prophylactic pollen injections had resulted in an estimated 50 per cent relief. Another summer of phylactic treatment had given him somewhat less relief. He was given 0.5 cc. of viosterol 10,000 X by mouth daily. His estimated degree of relief, confirmed by frequent observation and questioning, was 90 per cent.

The other four patients in this group all had autumnal asthma complicating their hay fever. The following protocol of one of them is given while the histories of the others are summarized more briefly.

Chart 4.—The effect of viosterol (10,000 X) on the calcium, inorganic phosphorus, potassium and the potassium/calcium ratio in a patient with seasonal hay fever and asthma: 1. 1.05 cc. viosterol 10,000 X daily by mouth. 2. 1 cc. viosterol 10,000 X daily by mouth. 3. 1.5 cc. viosterol 10,000 X daily by mouth. 4. 0.6 cc. viosterol 10,000 X daily by mouth. 5. 0.3 cc. viosterol 10,000 X daily by mouth. O, administration discontinued; A, very mild nasal symptoms; B, nausea and vomiting; C, moderately severe hay fever symptoms.

M. N., a woman, aged 25, had autumnal hay fever for twenty years associated with asthma (autumnal) for eighteen years. She had preseasonal injections of pollen during the previous three years with an estimated 50-per-cent relief each season. Control blood samples were drawn on July 11, 14 and 18. Treatment

with 0.5 cc. daily of viosterol 10,000 X by mouth was begun on the last day. Blood was drawn semiweekly after that (chart 4). August 8, the dose was increased to 1 cc. daily. Abdominal cramps and nausea developed. She varied the daily dose from 1 to 1.5 cc. until, August 21, she was complaining of nausea and vomiting frequently, but attributed this to the daily consumption of a quart of milk. Because of these symptoms she finally discontinued taking the viosterol from August 25 to August 29. After that she varied the dose between 0.3 and 0.5 cc. Even with this dose she occasionally developed slight nausea and was compelled to reduce the dose further to an amount varying from 0.15 to 0.3 cc. daily until September 23, when the administration of viosterol was discontinued permanently.

Moderately severe hay fever symptoms were present August 16 and 17, following a golf game. No symptoms were present thereafter until August 22, when again, after an afternoon on the golf course, she had moderate hay fever for the next two days and severe symptoms on the third day. Slight nocturnal asthma was present from August 25 to August 29. The chest, on examination in the daytime, was normal during this period. At this time the patient stated that so far she had been protected to a degree of more than 75 per cent as compared to a season without treatment. From then on she had only slight to moderate hay fever daily until September 17. After that she was free of symptoms. At the end of the season she again claimed to have had about 75 per cent relief and was certain that the degree of relief was greater than she had previously had from prophylactic injections of pollen.

The second patient of this group was a woman, aged 25, who had developed symptoms during August, 1931, for the first time. Her asthma was severe and lasted from August 20 until November. She had no treatment other than palliative measures during that period. With viosterol in doses varying from 1 to 0.3 cc. daily she estimated that she had 75 per cent relief during the 1932 season.

Another patient, a woman, aged 32, had autumnal hay fever and asthma for fifteen years. From September 1 to October 1, every year, the asthma was practically continuous and so severe that she had to rest in a chair during the night. She had lost 15 pounds (6.8 Kg.) during this period each year. No other except palliative treatment had previously been tried. She was able to take from 0.5 to 2 cc. of viosterol 10,000 X daily. Only one severe asthma attack and nine mild nocturnal attacks occurred during the season. She lost only 4 pounds (1.8 Kg.) during the period. Her estimated degree of relief was 80 per cent.

The fourth pollen asthma patient was a woman, aged 25, who had had this complaint since early childhood. During the preceding two years she had had only slight relief from intensive prophylactic treatment given in our allergy clinic. The amount of viosterol 10,000 X was at first 0.5 cc. daily. This was later increased to 2.5 cc. daily. Her asthma was much milder than during previous seasons. She estimated a degree of relief of 75 per cent.

COMMENT

The attitude in the medical profession toward the administration of viosterol of high potency is strongly conservative. Judging from experience in this institution this attitude need no longer be so conservative. The early symptoms of overdosage are easily recognizable and apparently the subjects recover readily without permanent injury.

The most common early symptom is nausea, sometimes accompanied by vomiting and less frequently by abdominal cramps and diarrhea. Later symptoms are headache, muscular weakness, pain in the muscles and joints, dizziness and occasionally numbness and tingling in the extremities. These symptoms are not distinctive, but it appears probable, when they occur in a subject during the administration of viosterol and disappear on discontinuing the administration of viosterol or on reducing the dose, that they are due to the treatment. They may occur singly or in any combination. In fact, the same subject may display very different symptoms at different times.

So far as we have been able to determine, there are no criteria by which a subject's susceptibility to toxic action may be discovered in advance. Certainly the blood studies give no indication of the imminence of toxicity, either in animals or in human subjects. One peculiar manifestation is that the tolerance of the same subject seems to vary at different times, quite independent of correlation with any observed factor. In general, of course, there is *usually* pronounced hypercalcemia with toxicity, but the correlation is not invariable.

The route of administration is of some interest. In animal experiments the practice was instituted four years ago of injecting the oil solution intravenously.¹² Subsequently this method was adopted by Reed and Seed¹³ in human patients and in the earlier studies reported in this paper. In normal and parathyroidectomized dogs and in tetany patients the material appears to be more effective when given in this manner than by the oral route. This difference appears to be purely quantitative rather than qualitative and is probably due, first, to incomplete absorption of the ingested material and, secondly, to partial reduction to coprosterin in the intestine.

Many investigations have indicated that the absorption of calcium from the intestine is facilitated by viosterol, but there is no evidence that this is due to its local application by ingestion. On the other hand, we have some evidence to be reported later that this effect is produced quite as readily by intravenous administration.

Still further, the accelerated mobilization of calcium in the blood can be demonstrated when no calcium is ingested. All of this points to an intrinsic locus of action of viosterol.

That the intravenous injection did not produce as profound effects on the calcium-phosphorus metabolism in the earlier series as did the oral administration in the more recent study might be interpreted as contrary to these statements. However, attention is called to the fact that the total amount administered in the second series was much greater than that in the first, and it is probable that this alone would explain the apparent discrepancy.

The changes in the blood calcium and potassium in this entire group, especially in the hay fever patients, showed characteristics that are striking because of their uniformity. During the control period there were marked fluctuations in the blood calcium and potassium, especially in the latter. Differences as great as 3 mg. per hundred cubic centimeters in the calcium range were found in the same patient on different days before

13. Reed, C. I., and Seed, Lindon: The Treatment of Clinical Tetany with Irradiated Ergosterol, *Endocrinology* 17: 136 (March-April) 1933.

treatment was initiated. The potassium range varied even more during this period, rising from the low level of 12 mg. on one day to 25.14 mg. per hundred cubic centimeters four days later in one individual. The resulting potassium/calcium ratio was very irregular on various days, falling from 4 to 1.8 mg. in a four day interval in one patient. In general, the ratio was high, usually above 2 mg. during the control period. This irregular, high potassium/calcium ratio was maintained for about two weeks following the beginning of viosterol administration. After that, a change occurred which again was fairly uniform in all six patients. The calcium increased—to concentrations above 18 mg. and 21 mg. in two of the patients. The potassium, while rising and falling slightly with the fluctuations in calcium, showed a definite tendency to remain relatively low and stable compared to the high peaks reached previous to treatment. The result is a relatively stable potassium curve. Occasionally, with a sharp rise in calcium the potassium level was actually lower than the calcium. This occurred one or more times during the observation period in four of the six patients.

The picture is even more clearly brought out as one follows the potassium/calcium ratio. This, as previously mentioned, was at first irregular with sharp fluctuations. About two weeks after the beginning of treatment, the curve became plateau-like, with only minor fluctuations. In addition, the tendency was toward a low ratio, almost constantly below 1.5, falling occasionally below 1.0 in all except one case, which was insufficiently studied.

The wide fluctuations of the calcium level in most of the patients during the control period when the blood was examined daily or at intervals of several days leads us to emphasize the fallacy of grouping patients as cases of hypocalcemia or hypercalcemia on the basis of one blood examination. The variability of these elements under normal conditions is shown by the work of Petersen and Levinson.¹⁴ In a group of 100 "normal" individuals they report a calcium range of 8.2 to 12.7 mg., a potassium range of from 16.6 to 27.4 mg. and a potassium/calcium ratio of 1.7 to 2.4.

While similar effects on the blood chemistry were produced by viosterol in all of our patients, the clinical results permit their division into two groups. The first group consists of the two patients with chronic urticaria of unknown origin and the three asthmatic patients whose symptoms were probably due to chronic respiratory infection. These were not improved by the treatment. The second group consists of the six patients whose allergic symptoms were caused by known inhalants, allergy of extrinsic origin. All of these were definitely benefited by viosterol treatment. It is possible that the underlying mechanism of asthma due to respiratory infection (intrinsic asthma) differs from that caused by inhalants (extrinsic asthma).

It is to be emphasized that our purpose in this preliminary work was to observe the effect on symptoms of marked changes in the calcium, phosphorus and potassium metabolism. To accomplish this, massive doses of viosterol, approximating the limit of tolerance in each patient, were given. To use such doses in the treatment of allergic conditions would not only be impractical but might in some cases be injurious. The marked disturbances in the calcium and potassium concentrations and relationship are so far from the

physiologic normal limits that they are not to be recommended. There is the danger in patients with arteriosclerosis, especially of the coronary arteries, of increasing temporarily the blood and tissue calcium to abnormal levels.

The effective dose of viosterol that will not produce marked changes in the potassium/calcium ratio and yet be of therapeutic value in allergic conditions is to be determined in future work. It is possible that the hypercalcemia produced is neither an index of the degree of benefit nor possibly even a cause of the improvement. The biologic effects of viosterol on other factors not determined in this work require study before any conclusion may be drawn as to what is responsible for the improvement in some allergic conditions when it is administered.

Only one of the six hay fever patients observed obtained complete or nearly complete relief. The others enjoyed what they termed marked relief. Four of the six had had severe asthma during previous seasons. All had asthma in spite of viosterol treatment. It was, however, much less severe than during any previous year. It would be presumptuous to make any comparison based on such a small group about the relative value of viosterol in massive doses compared to any other form of treatment of hay fever. It is our purpose in a later work to determine the effect of smaller doses of viosterol on hay fever patients with and without therapy with pollen extract. It is our belief at present that viosterol may prove to be of value as an adjunct treatment, especially in those who are not benefited by injections of pollen extract.

SUMMARY AND CONCLUSIONS

1. The effects of viosterol of high potency have been studied in a group of three patients with infectious asthma; a group of two urticaria patients and a group of six seasonal hay fever patients. Viosterol had no effect on the symptoms in the two patients with urticaria nor the three with chronic asthma due to respiratory infection. All hay fever patients were well protected during the season of 1932 as compared to symptoms during previous seasons; one was relieved almost entirely.

2. The blood calcium and potassium in allergic individuals determined on different days during control periods show marked variations in the same individuals.

3. Massive doses of viosterol raised the calcium to very high levels, lowered the potassium level, diminishing its wide fluctuations, and stabilized the potassium/calcium ratio at a relatively low level.

4. The threshold of toxicity varies in different individuals and may even vary in the same subject at different times.

5. Toxic symptoms are readily recognized and quickly abated on discontinuance or reduction of the amount administered.

Increase in Disseminated Sclerosis.—During the last decade disseminated sclerosis has undoubtedly occurred with increasing frequency, and at the present time few neurologists would challenge the statement that in this country it is now the commonest organic disease of the nervous system, not even excluding neurosyphilis. Although its etiology still remains obscure and but little progress has been made in either its prevention or treatment, some advance is apparent toward a better understanding of the clinical aspects of the disease.—*Problems of Disseminated Sclerosis, J. Neurol. & Psychopath. 13:227 (Jan.) 1933.*

THE USE OF DEHYDRATION IN
EPILEPSY

GEORGE WILSON, M.D.

PHILADELPHIA

AND

WILLIAM A. LIMBERGER, M.D.

WEST CHESTER, PA.

Rowntree¹ and his co-workers, in a series of papers the first of which appeared in 1923, pointed out the effect that extremely large amounts of water have on animals if given by stomach tube. Water intoxication is characterized by restlessness, asthenia, polyuria, diarrhea, salivation, nausea, retching, vomiting, muscle tremor and twitching, ataxia, tonic and clonic convulsions, frothing at the mouth, stupor and perhaps death. The symptoms given in the foregoing sentence can be prevented by the timely administration of hypertonic solution of sodium chloride. Signs of water intoxication could not be produced except rarely if the water was given by rectum, intravenously or directly through a fistula into the duodenum. Rowntree reported an increase in intracranial pressure in his one flawless experiment. Lennox and Fremont-Smith found no increase in the spinal fluid pressure either in an epileptic patient who drank 1,000 cc. of water as rapidly as possible or in one who drank 200 cc. every half hour until a total of 1,200 cc. was taken.

McQuarrie,² in 1929, wrote on the relationship of water balance to the occurrence of the seizures in epilepsy; he concluded that stringent restriction of fluids lead to dehydration of the tissues and prevention of fits. Suddenly increasing the intake of water, says McQuarrie, during the course of dehydration tends to cause recurrence of seizures, at least in severe cases. He thought that the disturbance of water balance, perhaps affecting the nervous system more specifically, appears to be closely identified with the etiology of epilepsy. Fay³ wrote along the same lines and put forward a mechanical theory of epilepsy.

Cameron⁴ carried out dehydration in a series of typical institutional epileptic patients and found that no improvement resulted. Riley⁵ gave his opinion that the dehydration theories in epilepsy were without merit and that he had never had any successful results in the control of seizures by limiting the fluid intake. Cobb⁶ does not deny that water restriction may be beneficial to some patients, or that water drinking may, in some cases, increase the number of attacks.

Since 1929, we have been testing the effect of hydration and dehydration in epileptic patients, the majority of whom have been patients in the Pennsylvania Epileptic Hospital and Colony Farm at Oakbourne, Pa. Most of them were "standardized," so to speak, as far as diet, habit of living, sedative drugs and work are concerned, and no changes were made (with rare exception) while the effect of varying levels of fluid intake was studied.

The patients were chosen from among the 130 residents of the colony farm, an attempt being made to select only those who had a reasonable amount of intelligence so that some degree of cooperation could be expected. There were eighteen women and five men in the group tested. The youngest person was 9 years of age, the eldest 55. Most of the patients had active epilepsy and averaged for the most part from 100 to 300 convulsions a year, although a few were more quiescent and had only a few fits yearly.

In six of the patients the fluid intake alone or, in addition, the fluid output was measured and recorded; in these cases no attempt was made to control the amount of fluid taken per day. In the remaining cases, in addition to recording the fluid intake and output per twenty-four hours, the patients were definitely instructed as to the amount of fluid allowed per twenty-four hours, whether the amount was high or low, and every effort was made to have these orders complied with.

The fluid intake included all the water, milk, fruit juices, broths and soups consumed by the patient, but no attempt was made to estimate the water content of the food eaten. Likewise, the fluid output was the total urinary output per twenty-four hours with no effort being made to estimate the fluid content of the feces or the water loss through perspiration or respiration.

When restriction of fluids was instituted it was discovered that some of the patients were consuming 16 ounces or less in twenty-four hours and one patient averaged an intake less than 10 ounces for twenty-four hours for a period of a month. When a patient was ordered on excessive fluid, he consumed 64 ounces or more a day. During the summer months it was extremely difficult to keep the patients on a restricted intake of 16 ounces or less. The patients were maintained for at least a month at a certain fluid level and were then changed or allowed to remain on the same fluid intake, according to the results obtained.

No patient is more difficult to control than an epileptic patient; this is so in every respect but especially in relation to his desire for food and drink. Some may have cheated on the low intake, but the figures given for those on forced fluids we know are reliable because the fluid was given by a nurse and drunk in her presence. The only manner in which an epileptic patient (or any one else) can be kept on an intake of much less than 500 cc. in twenty-four hours is to lock him up.

Attacks are recorded without an attempt being made to separate them into grand and petit mal; a fit is a fit, and the so-called minor spell is as potentially harmful as the grand attack—some think more so.

In most of the patients there was no definite relation to the number of fits and the fluid intake. In some, limitation of fluid seemed to decrease the attacks for a month or two, but if the amount of fluid was then greatly increased, some had a decrease of fits. Not infrequently, a patient on 2,000 cc. or more of fluid who was then abruptly placed on a restricted intake of 750 cc. had more attacks than when he was on hydration. One man who had been having from two to five attacks a month for the year before admission was given 1½ grains (0.1 Gm.) of phenobarbital and left to his own desire regarding fluid, except to measure the intake. He has had no attacks for ten months; his average daily intake in that time has been between 2,500 and 3,000 cc. If we had restricted his intake to

500 cc., what an addition he would have been to the dehydration theory!

One patient became extremely dull on hydration, and the condition cleared up on restriction of fluid to 500 cc., yet when that level of fluid was maintained and the sedatives (1½ grains of phenobarbital and 15 grains [1 Gm.] of sodium bromide in twenty-four hours) were withdrawn, he had a burst of seizures within two days. A woman, aged 26, was on a level of 558 cc. for two months and had three attacks; the following month the daily average was 651 cc. and she had 818 seizures; no change was made in the medication. In many cases a six months average of fits on low and high intake, compared with the preceding year's record, during which no restriction or forcing of fluid occurred, showed practically no difference.

Lack of space prevents the printing of the tables.

COMMENT

The treatment of epilepsy has remained one of the unsatisfactory phases of medical science. Any procedure, therefore, that will diminish the failures should be grasped and use made of it immediately. The very helplessness with which the treatment of this disease is viewed has made it possible for many "cures" to be brought forward, but, like the "snow flake on the river, a moment here then gone forever," they are soon relegated to the limbo of forgotten therapeutic endeavors. Who, now, even among the most radical of visionaries, recommends to an epileptic patient that he (a) have the colon extirpated or, as Peterson said, have it reduced to a semicolon; (b) have a hole made in the appendix and the colon irrigated; (c) have *Bacillus cinnamatus* eliminated from the gastro-intestinal tract; (d) be castrated (especially the female); (e) have the cervical sympathetic removed; (f) have the head opened on meager evidence; (g) have the actual cautery applied to the scalp, and, for a good result, the scalp burned down to the skull; (h) suffer various cerebral arteries to be tied; or—but why prolong such a recital? Yet many of the foregoing "cures" were the talk of their day and from time to time are reviewed or rediscovered by diligent readers of medical history. Thus, only recently an otolaryngologist of repute asked permission to perform turbinectomies on a series of epileptic patients. He had read some old papers on the subject and thought the procedure should be resurrected.

Is there any value to the epileptic patient in dehydration? To answer that question we have studied a large number of patients in the last four years, a few of whose records have been reviewed.

An occasional patient of ours did well on dehydration, but so also did an occasional subject seem to do well on an excess of fluid. Forcing fluid did not cause a burst of fits any more often than dehydration seemed to do. On a number of occasions we have tried the following test: A patient was placed on full dehydration and a brand of phenobarbital alone, or in conjunction with bromide; he was kept on that treatment for a month. Then he was given 2,000 cc. or more of fluid in twenty-four hours for a month and the same dosage of drugs was continued. Little or no change resulted in the number of fits though the change was often downward. The patient was then put back on dehydration and the sedatives were withdrawn. As a rule, a series of seizures occurred, not infrequently of a severe status. Fetterman and Kumin⁷ have had a

similar experience. In six instances we had epileptic patients drink large quantities of water, from 1,000 to 2,000 cc. in a few minutes, and they did not show an increase of fits.

The earlier an epileptic patient is seen after his first attack and the sooner treatment is instituted, the better will be the result, at least temporarily. Many children who have had convulsions go for months or even years without any medication or treatment, and without fits. If a few such patients are grouped under any plan of treatment, misleading conclusions may be drawn. A new treatment is often tried in conjunction with all forms of therapy thought to be of value in the disease, and any improvement that occurs to the patient is attributed to the "new" and not to the combination of things. Such is the case in the treatment of epilepsy.

CONCLUSION

Dehydration may be of service in the treatment of some epileptic patients if combined with other accepted forms of therapy. By itself, it is not of much value. Status may develop in patients on extreme degrees of dehydration. Bursts of fits do not occur regularly or frequently if large amounts of fluid are given after a period of dehydration.

133 South 36th Street—301 South Church Street.

EMBRYONAL CARCINOMA OF ABDOMINAL TESTIS IN A PSEUDOHERMAPHRODITE

A. P. VASTOLA, M.D.

WATERBURY, CONN.

The rarity of this case prompts me to record it. It is recorded also because it demonstrates the value of the Aschheim-Zondek test in determining the post-operative prognosis of a malignant growth of the testicle.

History.—F. T., aged 33, consulted me for a congenital anomaly in 1917. His parents, three sisters and two brothers had no physical abnormalities. The past history was irrelevant. His social, physical and sexual inclinations were masculine. He was shy mannered and hypersensitive about his physical defect. His height, weight and muscular development were below the average for his age. Although his voice, skin, body contour and distribution of pubic hair were decidedly feminine, his breasts were those of a male. The genitalia consisted of a rudimentary imperforate penis, which was fixed firmly to a median raphe extending below to a bifid scrotum, each half of which resembled a labium majus. The penis, which appeared more like an enlarged clitoris, lacking mobility, had no physiologic function. In the middle of the cleft dividing the scrotum was a small vaginal introitus about one-half inch deep, which admitted the tip of the index finger. The urethral opening, in position and appearance, was similar to that in a female. There were no testes palpable in either the scrotum or the inguinal canals, and rectal examination did not reveal a prostate. I classified the patient as a pseudohermaphrodite.

In 1919, he was operated on for an acute suppurative appendicitis and for obvious reasons his pelvis was not explored to determine the character of his generative organs.

Nine years later he underwent a plastic operation to relieve him of painful erections and to enable him to have coitus. The results of this procedure were most gratifying to the patient, as they converted him from a dejected, impotent individual into a happy and sexually active one.

Oct. 1, 1932, at 8:30 a. m., I was called to see him for the unusual surgical condition described in this report. Inquiry disclosed that at 7 o'clock in the morning he was seized with

7. Fetterman, J. L., and Kumin, H. J.: *Dehydration in Epilepsy*, J. A. M. A. 100: 1005 (April 1) 1933.

sudden agonizing, cramplike pains, localized at first below the umbilicus and later becoming generalized throughout the abdomen. An uncontrollable vomiting and a clammy profuse perspiration supervened. He stated that he had sustained no injuries, that his bowel movements had been normal, and that

Fig. 1.—Female distribution of pubic hair, underdeveloped penis and bifid scrotum in a male pseudohermaphrodite.

for six months the lower part of the abdomen had been getting larger and, although it felt quite hard, had never been painful. His appetite throughout had been fairly good and there had been no loss in weight. The patient, during my interrogation, brought up at intervals a bile-stained watery vomitus.

Physical Examination.—Since his plastic operation the masculinity of the patient had become more pronounced. His chin was covered with a thin beard; his muscles were appreciably developed and the genital organ had doubled in size. He was lying on his back, with knees flexed and both hands holding the lower part of his abdomen. The mucous membrane of his lips was slightly cyanotic, the skin pale and his facies pinched. His pulse was 70 to the minute; the rectal temperature was 97.4 F. With the exception of a weak apex beat, nothing abnormal was found in his heart or lungs. The abdomen showed a scar lateral to the right rectus and a very prominent uniform swelling rising from the pubic region, in the midline, to about 1 inch below the umbilicus. Spasm of the rectus muscles over a hard, smooth and slightly movable tumor mass was very marked. Percussion over the mass elicited pain and a flat note; above and to either side it produced a slightly tympanitic sound but no evidences of free fluid. The liver and spleen were not enlarged. Rectally, a doughy painful mass, slightly movable and apparently not a part of the large bowel, could be readily palpated. The inguinal, axillary and supraclavicular glands were not enlarged, and there were no points of tenderness found over the palpable bones of his body. The bladder was distended. The reflexes were all normal. A provisional differential diagnosis was made between a malignant growth of an abdominal testis and torsion of an ovarian cyst.

On admission to the hospital his rectal temperature was 98 F., and the pulse 60 to the minute. A blood count showed red blood corpuscles, 3,800,000; hemoglobin, 65 per cent (Tallqvist); color index, 0.8; white blood corpuscles, 10,900; polymorphonuclears, 80 per cent; lymphocytes, 20 per cent; blood type II, Moss classification. A urinalysis showed nothing abnormal. Roentgenograms of the lungs, heart and abdomen disclosed nothing abnormal.

As the patient had been unable to empty his bladder completely prior to his present illness, he was catheterized under a general anesthetic. Thirty ounces of a concentrated urine was obtained and the pain was temporarily relieved. His condition in the ensuing twenty-four hours became progressively worse.

On the morning of October 2, the attending genito-urinary surgeon, Dr. McPartland, and I examined him. Since first being observed he had acquired a ghastly pallor; his breathing was shallow and dyspneic, and his pulse was barely perceptible. The abdomen, boardlike in rigidity, gave rise to excruciating pains when pressed. Following a second catheterization by Dr. McPartland, which did not relieve him, he was given intravenously 1,000 cc. of a 5 per cent dextrose solution and prepared for an exploratory laparotomy.

At 3 p. m., under local procaine hydrobromide and gas-oxygen anesthesia, a laparotomy was performed through a mid-right incision. When the peritoneum was incised there was an immediate and uncontrollable gush of blood, which poured from all parts of the abdominal cavity. An exploration of the pelvis disclosed a tear about 4 inches long in the posterior surface of a pelvic tumor, the pedicle of which was attached to the peritoneum in front of the right iliac vessels and had undergone torsion. Fortunately, a part of the omentum had forced itself into the rent and so, acting as a plug, had partially controlled the bleeding. The pedicle was rapidly

Fig. 2.—Urethral opening and cleft dividing the scrotum in a male pseudohermaphrodite.

untwisted and cut between two clamps placed at its base, and the tumor was quickly delivered and ablated. The stump was then ligated with number 3 chromic catgut. Being informed by the anesthetist that the patient was pulseless, colorless and dyspneic, we made no attempt to ascertain the absence or presence and nature of other generative organs. Two

cigaret drains were placed in the pelvis and the wound was closed in layers. A transfusion of 600 cc. of citrated blood was immediately given, followed by 1,000 cc. of physiologic solution of sodium chloride intravenously.

On his return to the ward, the patient was placed in a shock position and given 1,000 cc. of 5 per cent dextrose in the subpectoral regions. He reacted well to the measures employed for combating the operative shock.

Postoperative Treatment.—A continuous rectal drip was instituted, consisting of 5 per cent dextrose and sodium bicarbonate; to relieve his vomiting, gastric lavage was done through a Levine tube, and to restore his fluid volume 1,000 cc. of physiologic solution of sodium chloride was given intravenously twice a day. A few days after the operation he was placed on a liver diet, and iron was given after meals. He was discharged from the hospital, November 2, in good condition.

Feb. 4 and 18, 1933, an area 20 inches square on the anterior part of the pelvis and February 11 and 25 on the posterior part was given roentgen irradiations. A voltage of 200 kilovolts was used. The filter was 0.5 mm. of copper with 1 mm. of aluminum. The distance from target to skin was 43 cm.

Pathologic Examination.—The specimen consisted of a globular tumor 15 cm. in diameter, having on its smooth surface

Fig. 3.—Embryonal carcinoma of abdominal testis in a male pseudohermaphrodite. Specimen unopened.

a tear 10 cm. long, which extended into its body. Attached to the surface opposite to the tear was a pedicle 6 cm. in length and approximately 2 cm. in diameter with constrictions on it suggesting torsion. When the tumor was opened it showed a rough irregular cavity the inner wall of which was very irregular and composed of chocolate brown, friable tissue. The walls of the cavity measured from 1 to 3 cm. in thickness, and when sectioned the tissue was soft, very friable and mottled chocolate brown and dark red. Sections were taken from various portions of the mass for histologic examinations.

Microscopic examination was done by Dr. James Ewing, who reported that sections showed a diffusely growing, large round and polyhedral cell carcinoma. The tissue was very soft and the stroma delicate and infiltrated with lymphocytes in many places. Dr. Ewing thought this a rather typical teratoid cancer and of teratoid origin not derived from adult tubule cells, as tumors that may possibly originate from tubule cells and may be called seminoma generally are more alveolar in structure and lack lymphoid stroma. Yet he stated that he would not insist too strongly on the exact derivation of this particular tumor, which impressed him as an embryonal growth.

December 1, the Aschheim-Zondek (Friedman modification) reaction was negative.

January 6, February 15, March 17 and April 11, Dr. Russell S. Ferguson did a quantitative test and reported that at each assay he found 100 mouse units of prolan A per liter of urine.

That amount, he stated, was consistent with clinical cure for the type of tumor which the patient had.

Summary.—A male pseudohermaphrodite, aged 33, with retained abdominal testes, developed the symptoms of an acute condition of the abdomen associated with severe shock. Physical examination showed rigidity of the rectus muscles and a tumor mass rising from the pelvis nearly to the umbilicus. There were no clinical evidences of metastases. Exploratory

Fig. 4.—Embryonal carcinoma of testis; reduced from a photomicrograph with a magnification of 125 diameters.

laparotomy revealed torsion of the pedicle of an embryonal testicular carcinoma which had ruptured and bled in the abdominal cavity. The patient recovered from the operation and had a negative Aschheim-Zondek reaction over a period of six months. This, together with the fact that he had no symptoms of recurrence or metastases, pointed to a clinical cure of his condition.

Fig. 5.—Embryonal carcinoma of testis; reduced from a photomicrograph with a magnification of 125 diameters.

COMMENT

An exhaustive search of the literature has not disclosed a similar case. The primary purpose of this report, however, is not to discuss statistics nor to consider the etiology, pathology and treatment of testicular neoplasms but rather to emphasize the dangers inherent in abdominal testes and to advocate periodic examinations of individuals with such anomalies and the use of the Aschheim-Zondek test for the purpose of detecting malignant conditions much earlier.

The Aschheim-Zondek reaction, from a study of a preliminary report by Ferguson and his associates,¹ is a reliable test for differentiating between malignant and benign neoplasms of the testicles. It is also valuable in detecting postoperative recurrences or metastases and observing the results of roentgen therapy in such cases. Dr. Ferguson stresses the importance of injecting the extracted hormone into female immature mice in order to observe the reaction. He found that the quantitative tests, as ordinarily performed on the rabbit, are of little value, as the excretion in two thirds of the cases is less than that required to activate the rabbit ovary.

PNEUMOCOCCIC INFECTION OF THE SACRO-ILIAC JOINT COMPLICATING PREGNANCY

TREATED BY RADICAL RESECTION OF THE ILIUM

FREMONT A. CHANDLER, M.D.

CHICAGO

Acute pyogenic infections of the sacro-iliac joints have long been recognized as severe menaces to life. The extension into the fascial planes of the pelvis and the development of an osteomyelitis of the ilium

Similar cases may have been reported under indefinite titles, but these are not available for review. No reference of such an infection complicating pregnancy was found. The following two cases of pneumococcic infections of the sacro-iliac joint complicating pregnancy are reported because of the apparent rarity of such involvement of this joint, the difficulty of diagnosis and the successful results following radical measures employed to promote drainage.

REPORT OF CASES

CASE 1.—E. H., a white woman, aged 20, married, was admitted to St. Luke's Hospital, in the gynecologic service of Dr. H. O. Jones, Jan. 19, 1932. Her chief complaint consisted of pain in the right leg of two days' duration and vaginal bleeding, which had been present for two and one-half weeks. She had had an abortion done by a midwife, January 3. The abortion being incomplete, the patient began to bleed about one week later, and this bleeding continued for about four days. She had felt quite well generally until January 15, when she began to complain of pain in the region of the right hip. This followed a run of a short distance and gradually became more severe. A local physician was called and a diagnosis of pelvic infection following abortion was made. Her temperature at this time was noted to be 102, and she was put to bed and given a sedative.

A general examination and history revealed no essential factors other than the pain located in the lower part of the abdomen, the region of the right hip and buttock. Her tem-

Fig. 1 (case 1).—Pelvis essentially normal except for narrowing of right sacro-iliac joint line and some loss of definition of the iliac margin in the lower half of joint, Jan. 20, 1932.

Fig. 2 (case 1).—Pelvis normal except for increased area of bone absorption, the lower half of the right sacro-iliac joint on the iliac surface, Feb. 1, 1932.

Fig. 3 (case 1).—Area of resection of the iliac portion of right sacro-iliac joint, permitting free drainage of abscess involving iliacus muscle, March 7, 1932.

or sacrum is to be anticipated. Because of the deep location of the sacro-iliac joint and the thick soft tissue covering of this region of the pelvis, diagnosis is difficult and is usually not made until after the infection has extended beyond the confines of the joint and involved the pelvis, the buttock, the hip and even the thigh. Statistics relative to such infections are few, but those found in the literature all verify the severity of the infection of the sacro-iliac joint and point to a high mortality as well as a high morbidity. It is obvious, therefore, that such infections should be recognized early and treated in such a manner as to prevent extension into the ilium and into the fascial planes of the pelvis.

Although pneumococcic infections of the major joints are rather uncommon, many are reported, most frequently complicating pneumonic processes. In a review of the literature since 1860, no case of pneumococcic infection of the sacro-iliac joint was found.

temperature was 99.8; pulse, 88; respiration rate, 22. The blood count, made January 20, showed: erythrocytes, 3,590,000; leukocytes, 26,850, and hemoglobin, 65 per cent. Vaginal examination revealed an exudate in both broad ligaments, and a diagnosis of postabortion pelvic cellulitis was made. Because of the pain in the region of the right buttock and leg, orthopedic consultation was requested.

January 20, the patient was still complaining of pain in the region of the right buttock, with some radiation down the posterior aspect of the right thigh. Motion of both hips, knees and ankles was normal. There was no local tenderness except over the general region of the right buttock and to some degree over the posterior aspect of the right sacro-iliac joint. The circumference of the thighs, knees and calves were equal on the two sides. Reflexes were normal. Lateral compression of the iliac crests caused excruciating pain in the region of the right sacro-iliac joint. On repetition of this test, no pain was referred to this area. There was a general lack of flexibility involving the entire lumbar spine, of a protective nature. Roentgenograms were ordered. The patient was placed on a fracture bed with traction to the right leg, the foot of the bed being elevated. Local heat was applied to the posterior aspect of the right hip and buttock. This resulted in considerable relief of the discomfort. Roentgenograms showed some thinning of the right sacro-iliac joint space and some lack of bone

1. Ferguson, R. S.; Downes, H. R.; Ellis, E., and Nicholson, M. E.: Preliminary Note on New Method of Differentiating the Testicular Tumors by Biologic Means, *Am. J. Cancer* 15:835-843 (April) 1931. definition of the right sacro-iliac joint. There was no fullness or induration suggesting local reaction to infection.

January 22, an exploratory needle was inserted into the inferior aspect of the right sacro-iliac joint, through the upper medial portion of the right buttock. Thick, greenish yellow pus was obtained and flowed freely from the exploratory

Fig. 4.—Operation for radical drainage of the right sacro-iliac joint: a, posterior superior spine of ilium; b, ilium; c, sacrum.

needle. The needle was kept in situ and used as a guide for an incision, which was made through the fibers of the gluteus maximus muscle, exposing the lower portion of the right sacro-iliac joint. About 1 ounce of pus was released. The joint was explored with a blunt instrument and a drainage tube was sutured in place. The wound was packed with petrolatum gauze. Cultures from the pus obtained revealed pure culture of pneumococcus, this being identified by subcultures. The patient's temperature fluctuated from 100 to 102, and her pulse remained about 120. During the next ten days, the drainage was profuse. The patient felt very comfortable except for tenderness of the wound. Her temperature remained elevated, varying from 100 to 103 F. Ten days following its insertion, the drainage tube was removed.

January 28, it was noticed that a smooth mass was palpable in the right iliac fossa and that the iliac glands on the right side remained large and tender. Vaginal examination by Dr. Jones revealed no change in the pelvis suggestive of a residual exudate. The temperature remained elevated and, as it was not compatible with complete drainage of the right sacro-iliac joint, the sinus tract was probed, January 31, and some serosanguineous discharge was obtained. At this time, restriction of internal rotation of the right hip was noted and a semifluctuant mass was felt in the region of the lower right quadrant, extending above the crest of the ilium in the general region of the psoas muscle. The mass was still present in the right iliac region, February 3, and on bimanual palpation suggested an abscess. Two days later, posterior drainage of this iliac abscess was done. An incision was made over the margin of the posterior aspect of the right iliac crest. The lateral surface of the ilium was exposed by subperiosteal dissection of the outer surface of the ilium to the margin of the right sciatic notch. A block

of bone, 4 by 6 cm., was removed from the ilium, including the lower two thirds of the iliac portion of the right sacro-iliac joint (figs. 3 and 4). As this bone block was elevated from its position in the ilium, about 6 ounces of pus coming from the various portions of the iliacus muscle filled the wound. The incision through the ilium was extended anteriorly and laterally, and the drainage tube was inserted deep into the iliacus muscle. The wound was then packed with petrolatum gauze, without suture. The discharge from his area was profuse and persistently showed pneumococcus organisms. Ten days after this radical drainage, the patient's temperature was normal, and she was very comfortable except for tenderness at the site of the incision. The drainage tubes were removed on February 23, and the wound was packed with petrolatum. By March 4, the discharge had ceased and the patient was very comfortable, with a normal temperature. At this time the sinus was probed and no exposed bone could be felt. This sinus tract was permitted to close gradually.

The patient was allowed up on crutches, March 30. Her general condition was very satisfactory. As the sinus tract was healing very rapidly, she was discharged home, April 1. She has been seen regularly since that time in the dispensary. May 27, she was walking without crutches and without a limp; there was no tenderness in the region of the right sacro-iliac joint. The incision had closed completely and firmly. Roentgenograms showed partial closure of the opening through the right ilium in the region of the sacro-iliac joint. The patient was examined in January, 1933. The wound was firm and the scar well healed. There was no evidence of inflammatory reaction, no pain in the region of the sacro-iliac joint, and no lack of function about the right hip. There was no limp and not the slightest interference with the function involving the pelvis or the lower spine.

In this case I have not had an opportunity to establish any direct connection between the endometritis and the pneumococcic involvement of the sacro-iliac joint. Cultures of the cervical discharge were not obtained. There are, however, several cases in the literature pointing to pneumococcic infections of the uterus.

CASE 2.—L. B., a white woman, aged 28, married and in the eighth month of her second pregnancy, was admitted to St. Luke's Hospital in the obstetric service of Dr. James A. Gough,

Fig. 5 (case 2).—An area of bone destruction involving the lower portion of the left sacro-iliac joint, March 3, 1933.

Fig. 6 (case 2).—Area of left ilium excised, March 31, 1933. The roentgenogram has been retouched.

Feb. 18, 1933. She had been in excellent health until about two months prior to admission, when she had a succession of severe colds, resulting in an acute infection of the left antrum. This had been irrigated for four or five days, when the patient began to complain of a dull pain in the lower part of the buttock on the left side. The pain was constant and of increasing severity. No history of injury, strain or radiation of pain was obtained. Laboratory examinations on admission, February 18, showed: red blood count, 3,980,000; hemoglobin, 70 per

cent; white blood count, 21,000; blood pressure, 124 systolic; 72 diastolic. Her obstetric condition was normal in every respect other than for the acute infection of the left antrum and her complaint of pain in the left buttock.

I saw the patient in consultation, February 20. Examination revealed tenderness over the left buttock and posterior portion of the left ilium with a maximum point of tenderness at the upper border of the sciatic notch. No swelling or induration was present. Motion of the hip was free in all directions and was not painful except in the extremes of motion. The sciatic area of the thigh was not tender. Lateral compression of the iliac crests caused severe pain in the posterior buttock on the left. Abduction, rotation and longitudinal pressure of the right thigh resulted in increased discomfort in the left buttock.

February 20, the red blood count was 3,540,000; hemoglobin, 65 per cent; white blood count, 12,000; temperature, 99.6.

A diagnosis of probable acute infection of the left sacro-iliac joint was made. The patient was placed on a fracture bed with traction to the left leg. This gave considerable relief. The acute sinus infection, which was being irrigated daily, seemed sufficient to account for the slight elevation of temperature and the leukocyte reaction. Roentgenograms of the pelvis failed to reveal pathologic changes in the region of the sacro-iliac joint because of the overlying fetal head. As ten-

Fig. 7 (case 2).—Incision for radical drainage of left sacro-iliac joint.

derness persisted over the left sciatic notch, this area was aspirated, February 27, without any positive results being obtained. Labor began and the patient was delivered without difficulty by Dr. Gough.

A moderate secondary anemia continued as well as a leukocytic reaction of from 12,000 to 14,000.

March 3, an abscess of the left pharynx was opened. Cultures revealed a heavy growth of *Micrococcus catarrhalis*, *Streptococcus hemolyticus*, and *Streptococcus viridans*. Blood culture was negative.

March 3, roentgenograms of the pelvis showed definite evidence of a destructive process involving the sacro-iliac joint on the left side, especially the lower half. These conditions were more pronounced on the iliac side than on the sacral side of the joint. A definite area of bone destruction was present.

Because of the presence of acute infection of the sinus and pharynx, and the early puerperium, drainage of the sacro-iliac joint was delayed. Pain on compression of the iliac crests and referred symptoms on manipulation of the right leg had disappeared.

A rectal examination revealed a small abscess anterior to the left sacro-iliac joint.

March 9, operation was done, with radical drainage of the left sacro-iliac joint. An incision was made along the posterior half of the iliac crest to a point distal to the posterior superior spine. The posterior ilium was exposed by subperiosteal dissection to the level of the sciatic notch. An abscess

overlying the sacrum and region of the ilium adjacent to the sciatic notch was encountered. A large block of ilium including the lower two thirds of the iliac side of the sacro-iliac joint was then removed, and this opening extended anteriorly. About 8 ounces of thick yellow pus was liberated from within the pelvis. Large tube drains reaching to the abscess cavity within the pelvis were placed, and the wound was packed with paraffin gauze. Cultures from the pelvic abscess showed a heavy growth of pneumococcus, when grown under partial anaerobic conditions.

Drainage from the incision was profuse for five days. One drainage tube was removed on the fifth day after operation. The remaining tube was removed four days later. The paraffin pack has been changed every fourth or fifth day, care being used to prevent closure of the superficial portion of the wound. All areas of exposed ilium and sacrum were covered with healthy granulations two weeks following operation. A small amount of purulent discharge continued for several days. The depths of the wound closed in rapidly.

At this time the patient's general condition is excellent. There is no evidence of pelvic abscess or residual infection of the ilium or sacrum. The superficial wound is healing rapidly.

In this case the series of infections complicating pregnancy is most unusual. No direct relation between the sinus infection and the involvement of the sacro-iliac joint has been established, cultures yielding different organisms from these areas.

SUMMARY

Two cases of pneumococcic infection of the sacro-iliac joint complicating pregnancy were treated by radical resection of the ilium. One resulted in a complete cure one year after operation; there is satisfactory progress to date in the other case.

180 North Michigan Avenue.

TESTICULAR FIXATION IN TORSION OF THE SPERMATIC CORD

EDWARD J. OTTENHEIMER, M.D.

WILLIMANTIC, CONN.

AND

CHARLES Y. BIDGOOD, M.D.

HARTFORD, CONN.

Although torsion of the spermatic cord unquestionably occurs more frequently than the reported cases indicate, and although it results in the loss of the affected testicle in 80 per cent of cases, very little emphasis has been laid on operative effort to save the affected testicle, when possible, or, more particularly, the prevention of torsion on the remaining side.

The symptoms and signs of cord torsion have been so adequately described in the literature of the past decade that they are by now familiar to every one. We propose, therefore, to confine ourselves to a brief discussion of some phase of its etiology and to submit a plan of operative treatment that is designed to save a small percentage of involved testicles, i. e., those in which reduction of the torsion has been attained before necrosis occurs, and especially to remove the possibility of its occurrence on the opposite side.

There are two fundamental conditions which numerous observers, Campbell,¹ Colby² and others, hold to be basically responsible for the occurrence of torsion: a voluminous scrotum and a mobile testicle.

1. Campbell, M. F.: Surg. Gynec. & Obst. 44: 311 (March) 1927; J. Urol. 24: 22 (Jan.) 1928.
2. Colby, F. H.: New England J. Med. 203: 16 (July 3) 1930.

The first of these has received relatively scant attention—less, we believe, than its importance warrants—and, in the operation presented here, appropriate steps have been taken to correct it.

Hypermobility of the testicle is the result of insecure fixation due largely to one or more developmental defects. Roche³ asserts that 50 per cent of instances of torsion occur in incompletely descended testicles, and that a great many such testicles show inversion. He maintains that the reason for this is that inversion represents a purposeful effort by nature to place the testicle in the scrotum, in spite of an abnormally short cord, even if it must be there upside down. The result of this is that it hangs free in the tunica vaginalis, attached only at the superior pole, and is unbound on its posterior aspect by the mesorchium which it should have. He supports this theory by pointing out that a solid egg-shaped object will rotate freely if suspended by a cord from its upper pole, but, if hung by two cords, one at the upper and one at the lower pole, its mobility is greatly diminished. Therefore, Roche says, "torsion may be regarded as the result of muscular action on an abnormally mobile testicle, this abnormal mobility having a close developmental relation to imperfections in its descent."

This theory is a logical one and readily acceptable in those instances of torsion in which there is incomplete descent of the testicle, with inversion; but many a fully descended testicle suffers from torsion of its cord, and the prevalent opinion is that this is allowed to occur because of hypermobility, due either to an abnormally lax mesorchium or to a redundant gubernaculum, in addition to a voluminous scrotum. Be that as it may, hypermobility, whatever its cause in any individual case, is undoubtedly the principal factor predisposing to torsion. In our case it was obvious that the hypermobility of the testicle was due to a redundant scrotal sac, in addition to an extremely long spermatic cord. Furthermore, it was noted that this condition was present also on the unaffected side. This we believe to be highly significant, when considering any form of treatment, since hypermobility, whatever the cause may be, is developmental rather than acquired and is therefore probably more often bilateral than has hitherto been suspected.

Since the literature on this subject demonstrates that almost every case of torsion eventually terminates in orchidectomy, the significance and importance of this fact become at once apparent. The case reported by Walker,⁴ in which orchidectomy had to be performed on a patient with an atrophied testicle on the opposite side, presumably, from the history, as the result of previous torsion, is evidence that, in any plan of treatment, the unaffected side should be carefully examined and, if found to be abnormal, some form of prophylactic surgery should be seriously considered. The following case is illustrative:

History.—C. B., a boy, aged 9 years, entered St. Joseph's Hospital, Willimantic, Jan. 17, 1933, complaining of pain in the left scrotum. The family and past histories were essentially unimportant. The present illness began eight days before admission. While running to school, he was seized with violent pain in the left scrotum, which was followed by nausea and vomiting. He was carried to a physician's office very soon afterward, where he continued to vomit and to have excruciating pain. During the examination of the scrotum, the pain suddenly disappeared and the vomiting ceased. In the sub-

sequent week he remained perfectly well, having no pain or discomfort in the scrotum. Eight days later, however, while sitting at his desk in school, he was seized again with the same severe pain, which was again accompanied by nausea, vomiting and chilly sensations, and a few hours later he was admitted to the hospital.

Examination.—At the office during the first attack the patient was in more or less shock. He was pale, the skin was cold and clammy, and his facial expression indicated great distress. Examination of the left scrotum showed a tender mass, which on palpation felt like an acutely inflamed epididymis. While this mass was being examined, it suddenly disappeared and the patient's general condition improved almost instantly.

Physical examination at the hospital showed that the patient was well nourished. He gave an intelligent history. He was pale and rather cold. The pupils were equal and regular and

Fig. 1.—Initial steps in second operation.

reacted to light. The sclerae were clear. The teeth were good and the tonsils had been removed. The tongue was moist and not coated. There was no general adenopathy, and the thyroid was not enlarged. The heart was not enlarged and there were no murmurs. The lungs were clear and resonant. The abdomen was normal. There was no evidence of any hernias. The scrotum was voluminous on both sides. In the left side of the scrotum there was a marked increase in the tension of the left testicle, and a tender mass the size of a walnut was present in the region of the epididymis. The right testicle seemed normal except that it was unusually mobile, apparently from a long spermatic cord. The length of the cord on the left side was not determined because of marked tenderness present.

A diagnosis of torsion of the spermatic cord was made, but operation was deferred. Over night the scrotum became very edematous, although the pain had subsided considerably. Operation was therefore decided on.

Operation.—January 15, under light ether anesthesia, through a small inguinal incision, an orchidectomy was performed. The

4. Walker, Kenneth: Brit. J. Urol. 3: 436 (Dec.) 1931.

testicle and epididymis were a dark purple. A definite point of torsion above the epididymis could be made out (fig. 3). The spermatic cord seemed unusually redundant above the constricting area. The cord structures were ligated and the wound was closed with interrupted catgut and silk.

Convalescence was uneventful and the patient was discharged from the hospital, January 26.

Because of the demonstrable redundancy of the scrotum and the unusual length of the spermatic cord on the opposite

The sutures on each side of the epididymis were tied and the testicle was thereby anchored firmly in the scrotum, pointing anteriorly, as it is in the normal position. These sutures were so placed that they did not in any way constrict the epididymis or vas (3, fig. 2). The wound was then closed with interrupted sutures of catgut to the dartos and of fine silk to the skin, and when this was done the testicle fit snugly in the scrotum because of the partial ablation. The patient's condition at the end of operation was satisfactory.

The patient was discharged from the hospital ten days later in good condition.

COMMENT

Fixation of the testicle in the scrotum has been done previously several times by various men. Keyes⁵ reports having anchored the testicle in the base of the scrotum in several cases; he believed that absence or redundancy of the gubernaculum was the prime factor in torsion of the spermatic cord. Campbell operated on the uninvolved side five times in fifteen cases, and says: "The mate of an involved scrotally contained testicle is often found to possess abnormal mobility," and Roche advises an operation essentially similar to the one performed here but does not cite an instance of having done it.

This fixation operation combined with partial scrotal ablation, when indicated, seems to us to be surgically sound. Its technic is very simple, and potential dangers are practically nonexistent. Its chief benefit is that it frees the patient from the possibility of torsion of the spermatic cord to the only testicle he possesses, and it is recommended in all cases in which hypermobility can be demonstrated in the uninvolved testicle, when torsion of the cord has occurred on the opposite side.

In addition, this case, as well as others cited in the literature, shows that torsion can occur and then disappear, either spontaneously or by manipulation, in a relatively few minutes. Since recurrence, however, is almost inevitable, we believe that in these cases, if seen

Fig. 2.—Further details of second operation.

side, we felt that some step should be taken to prevent torsion on this side, thus endangering the loss of the only remaining testicle. Accordingly, the patient was readmitted to the hospital, February 13, and operation was performed, February 16.

Second Operation.—Under gas-oxygen-ether anesthesia, a semielliptic incision was made in the right scrotum, beginning just below the external inguinal ring on the lateral aspect of the scrotum as far as the base. It then curved medially and was extended almost to the midline, and at this point upward and slightly lateral to the point of its starting (3, fig. 1). This incision was carried through the entire thickness of the scrotal wall, exposing the spermatic cord and testicle. The scrotal wall encompassed by this incision was then excised.

The testicle was readily delivered and found to be normal in size, shape and consistency. The epididymis was normal, as was the spermatic cord, except that the cord was redundant and very much longer than normal (4, fig. 1). The visceral tunica vaginalis was opened and everted, and the cut edges were sutured behind the epididymis.

The spermatic cord was pushed well up into the inguinal canal until there was no redundancy of it in the scrotum and was anchored there by three interrupted mattress sutures of fine silk (2, fig. 2).

The testicle was rotated laterally, and mattress sutures of fine silk were placed in the capsule of the testicle about 0.5 cm. in front of the epididymis, and in the medium septum of the scrotum (1, fig. 2). These sutures were left untied for the moment. The testicle was rotated medially, and similar sutures were placed, involving the lateral wall of the scrotum and the lateral aspect of the capsule of the testicle, again about 0.5 cm. in front of the epididymis (2, fig. 2).

Fig. 3.—Point of torsion observed above epididymis.

very early, operation should be done immediately and fixation performed on both sides. Had this been done in our case immediately after the first attack of torsion, it is our belief that the testicle might have been spared. If the case is seen later, however, after the testicle has become gangrenous and the scrotum edematous, orch-

5. Keyes, E. L., Jr.; Collings, C. W., and Campbell, M. F.: J. Urol. 9: 519 (June) 1923.

dectomy must be resorted to, and at the same time the uninvolved side should be operated on, if it presents any of the anomalous conditions known to predispose to torsion of the cord.

Clinical Notes, Suggestions and New Instruments

REMOVAL OF SLENDER FOREIGN BODIES FROM THE STOMACH AND DUODENUM WITHOUT GASTROTOMY OR DUODENOTOMY

PAUL W. GREELEY, M.D., WINNETKA, ILL.

Recently two articles¹ have appeared in THE JOURNAL concerning the removal of foreign bodies from the stomach and duodenum. The methods described were very similar and, while not claimed to be original, are not often used and deserve further mention so as to emphasize the value of this type of procedure.

Briefly, the treatment consists in the passage of a catheter or small stomach tube through the mouth down into the stomach. Through an abdominal incision, the stomach is exposed and the foreign body "milked" into the tube. The tube is then withdrawn, taking the foreign body with it. The abdomen is then closed without the necessity of opening any hollow viscera.

This method is chiefly applicable to slender objects such as "Bobby Pins," hairpins and safety pins. An open safety pin can be closed by pressure through the stomach wall and converted into a slender body. A slight variation to this procedure was described by Huff² in 1930. A small piece of gauze is sewed into the eye of the rubber tube before it is passed into the stomach. The foreign body in his case was an open safety pin. This pin was fastened into the gauze and closed by palpation through the stomach wall. The tube and pin were then slowly withdrawn.

A modification of the procedure is given by Dudko and Brailowski.³ They describe a case of a 15 year old girl who swallowed a small nail. The nail became lodged in the duodenum. A duodenal tube was passed under roentgenologic control. Air was then blown into the duodenum and the nail finally dislodged, after which it was passed by way of the rectum four days later. They believe that the dilation of the duodenum by the instilled air was responsible in part for the final passage of the foreign body.

There may also be found in the literature several other removals by similar procedures.⁴ These successful attempts have either been forgotten or passed by unnoticed, and it would seem timely to refer to them here.

I have operated on two patients with a foreign body in the stomach. The first was an open safety pin in the stomach of a 3 year old boy. Three weeks before the operation, the patient told his mother that he had swallowed a pin. He was immediately taken to his physician and a flat roentgenogram was taken of the abdomen. An open safety pin was easily demonstrated near the pyloric end of the stomach. The boy was fed a diet consisting chiefly of large quantities of cabbage, green beans and celery, such as has been described by Sauer.⁵ A fluoroscopic check was made several times during the following three weeks but the pin was always found to be in the same position. Fearing that further complications such as perforation and peritonitis might arise, I thought it advisable to remove the pin by surgical intervention. In this case, I followed the

plan suggested by Huff. Under ether anesthesia, a left upper paramedian abdominal incision was made. The point of the pin could be palpated in the duodenum, and the head was apparently caught behind the pyloric sphincter. The pin was worked back into the stomach. A small size stomach tube into the eye of which a piece of gauze had previously been sewed was then passed. The pin was fastened to the end of the gauze and closed by palpation through the anterior stomach wall. The tube and pin were gently withdrawn, after which the stomach was returned to the abdomen and the wound closed by layers. The child made an uneventful recovery and to date, nearly two years since the operation, has been perfectly well.

The second patient was operated on, Aug. 18, 1932. A 2 year old girl was seen by her mother holding an ordinary hairpin. The mother turned her back for an instant, and when she came to take the pin away from the child the pin could not be found. Being alarmed and fearing that the child might have swallowed it, she consulted her physician, who advised fluoroscopic examination of the abdomen. Such a study revealed a small, thin hairpin in the pyloric end of the stomach, with prongs separated about 1 inch. After one month of conservative treatment with a bulky diet, the pin had not moved. It seemed better judgment to remove the pin than to run further risk of possible perforation. Under drop ether anesthesia, the abdomen was opened through an upper left paramedian incision. The stomach was delivered from the abdominal cavity and the pin palpated in the pyloric end with the prongs pointing distally. A number 24 F. rubber catheter was then passed by the anesthetist through the esophagus into the stomach, and the blunt end of the hairpin was passed into the eye of the tube by palpation through the anterior stomach wall. By gentle manipulation, the pin was then easily "milked" all the way into the catheter. The tube was withdrawn, taking the hairpin out with it. The stomach was returned to the abdominal cavity, and the wound closed by layers. The child made an uneventful recovery.

CONCLUSIONS

1. A method of surgical removal of slender foreign bodies from the stomach, which is here discussed, is especially valuable in children because it does not bring about the same potential dangers incident to opening a hollow organ.

2. Although no actual record could be found, the method should also be applicable to adults.

3. This treatment in no way alters the already established indications for surgical removal of foreign bodies from the stomach and duodenum.

PRIMARY HEMANGIO-ENDOTHELIO-SARCOMA OF THE LIVER

CHARLES S. WHITE, M.D., WASHINGTON, D. C.

The infrequency of hemangio-endothelioma of the liver probably warrants reporting such a case, but its recognition as a medical entity is almost impossible and consequently detracts from its clinical interest.

There seems to have been some confusion in the classification of several types of sarcomas and angiomas of the liver, although there is a great similarity in the microscopic picture. One gets the impression from the various pathologic descriptions that probably all have their origin in the walls of the liver capillaries, with great proliferation of endothelial cells and even the formation of many new blood vessels. The cells are morphologically sarcomatous in type and must be considered malignant, although in many of the cases no metastases were found, possibly because of the early death of the patient. In some of the cases reported more recently, metastases were found in the lungs, pancreas and retroperitoneal glands. The tumors have been termed angiomas, hemangiomas, endotheliomas, sarcomas, and various combinations of these. Foote¹ has dis-

nated them, I think logically, as hemangio-endotheliosarcoma. In none of the cases was a correct preoperative diagnosis made; no patient survived.

The following case came under my observation:

History.—Mrs. A. D., aged 31, married, the mother of three children, was admitted to George Washington University Hospital, Aug. 23, 1932, as the private patient of Dr. Purse. Her complaint was pain in the upper right quadrant of the abdomen. The family history was unimportant except that the mother had chronic pulmonary tuberculosis.

For the past six or eight months the patient had complained of feeling tired and had pain high in her back, between the scapulae, and had not been ill enough to seek medical aid. The loss of weight had been moderate. One week prior to admission, the patient had four attacks of severe abdominal pain, of a paroxysmal character, radiating to the right shoulder, and not attended with nausea or vomiting. On admission to the hospital, she did not appear acutely ill but seemed pale and exhausted.

Examination.—The physical examination at the time revealed no gross pathologic condition in the chest. The temperature was 101.4 F.; pulse, 104, and respiration rate, 20. The liver was palpable well below the costal border but was not tender. The patient was poorly nourished but not emaciated, pale but

Primary hemangio-endotheliosarcoma of the liver.

not jaundiced. The laboratory examinations made within two days after admission were as follows: red blood cells, 1,950,000; hemoglobin, 28 per cent; white blood cells, 10,200; segmented forms, 75; band forms, 3; juveniles, 1; basophils, 1; monocytes, 1; lymphocytes, 19.

The urine showed a faint trace of albumin and occasional hyaline and granular casts.

The cholecystographic examination by the oral method showed that none of the dye entered the gallbladder, and a large shadow seen was thought to be the right kidney or a gallbladder filled with fluid.

The patient appeared to be losing ground rapidly, coincidentally with the rapid increase in the size of the liver. She was operated on, August 26, three days after admission. I was unable to make a diagnosis that was consistent with the symptoms.

Operation.—Through a right rectus incision the liver was immediately visualized, and the operator was impressed by its increase in size and the presence of a number of purplish nodules, varying in size from about 1 cm. to 4 or 5 cm. in diameter. These growths were firm and distinctive to the palpating fingers. On section, they bled freely and did not look unlike a black raspberry. A tentative diagnosis of sarcoma was made, and the pathologist was called for a biopsy. Dr. Choisser made a diagnosis of metastasizing hemangioma while viewing the growth in vivo. The subsequent frozen section

microscopic diagnosis was hemangiosarcoma. The final report on paraffin section later was as follows:

"Grossly, the specimen consists of a small dark red irregular nodule removed from the surface of the liver. It is 1 cm. long, 0.75 cm. wide and 0.75 cm. in thickness. Its surface is glistening and on cut section it shows the presence of a recent dark red clot, which can be displaced on slight pressure. Microscopic sections show the specimen to be covered on two sides with a thin layer of liver tissue to which the Glisson capsule is firmly attached. A few centimeters from the surface, however, are seen large embryonic spindle shaped cells with hyperchromatic nuclei, many of which are in an active stage of mitosis. These cells appear in small nests or groups which tend to infiltrate the liver substance and also in long dendritic-like strands which surround immature blood vessels, which show the presence in some areas of early thrombosis and beginning organization. The tumor cells are of the sarcomatous type and are extremely active. The tumor is occasionally described as a metastasizing angioma, but from its structure and anatomic relationship, I am of the opinion that it is a definite hemangiosarcoma and highly malignant."

The gallbladder was distended and a drainage tube was placed in it for relief of pressure. A rather hasty exploration of the abdomen was done and several retroperitoneal glands were found enlarged. The patient lived about ten days longer.

Autopsy.—On the right side the liver extended below the crest of the ilium and on the left to the level of the first floating rib. The right lobe was markedly enlarged, mottled and literally studded with a fungating reddish yellow type of growth consisting of multiple nodules. These nodules projected from the liver and had no sunken centers; they were very vascular and bled easily. Section through the liver showed the tumor mass to be made up of locules containing dark venous blood. These locules were of various sizes and were peppered through the liver substance. Those that came to the surface bulged outward, in some cases, for about 0.5 cm. The liver was literally honeycombed with his growth.

The anatomic diagnosis, made by R. M. Choisser, was hemangiosarcoma of the liver with metastasis to the head of the pancreas, the retroperitoneal lymph nodes and the left lung.

This case neither points a moral nor adorns a tale. It does not present a group of clinical symptoms that offers any clue as to the underlying cause and could hardly form a basis for a rational diagnosis in similar cases. If one is left with any impression in this case, it is the enlargement of the liver, the acute and devastating anemia, and the progressive exhaustion of the patient.

Probably one of the best contributions to the subject was made by the late John Foote of this city, who collected eight cases up to 1919 and added one of his own. Foote believed the disease was one of infancy, as none of his patients lived beyond the first year of life. Spiegel² has since reported another case in a child. I have found three cases in adults since 1919. Foote has very properly suggested that the disease be termed hemangio-endotheliosarcoma, and pathologists endorse his sound deductions. He describes the disease in this way:

"Summing up the information gained from a study of these cases, we may define hemangio-endotheliosarcoma of the liver as a congenital disease manifesting itself by an enlargement of the liver and some digestive disturbances within three months after birth, and caused by rapid and unrestrained proliferation of the endothelium of the liver capillaries causing the formation of nodules on the surface of and within the liver and a rapid and progressive increase in the size of that organ with a fatal termination usually before the sixth month as a result of pressure and obliteration of liver tissue. Jaundice and ascites are not usually observed, and metastases are not found. The liver is purplish, and is studded with nodules varying in size from that of a millet seed to that of an egg, some of which are confluent. The nodules are lighter in color than the surrounding tissue, and are also seen throughout the liver in cut sections to be dark red in the center surrounded by a lighter colored ring."

Puhr,³ in a more recent paper, states that only twelve or thirteen certain cases have been reported and reports another

2. Spiegel, H. A.: Pedunculated Angio-Endothelioma of the Liver, Arch. Pediat. 46:188-192 (March) 1929.

3. Puhr, Ludwig: So-Called Primary Hemangio-Endothelioma of the Liver, Ztschr. f. Krebsforsch. 34:503-517, 1931.

in a man, aged 65, who had been complaining for six months but was seriously ill only two weeks. Jaundice was present. The liver weighed 2,800 Gm. and was studded with nodules of various sizes of bluish red, shading to dark gray. There was a secondary pancreatic involvement.

Bengolea and Velasco Suárez⁴ report a case in a woman, aged 22, in which the diagnosis of chorio-epithelioma was first made but later was found untenable because no tumor was present in the genital organs. The liver was easily palpable and a roentgen diagnosis of hydatid cyst was made. At operation the liver was found full of rounded red tumors. The histologic examination agreed with descriptions of angioplastic sarcoma of the French nomenclature.

Since Foote's paper in 1919, additional data, chiefly from the German literature, cast doubt on points emphasized by him. It is not necessarily a disease of childhood, and in at least three cases metastases were present. The fulminant type of the disease probably explains the failure to metastasize. The patients, in many instances, succumbed while the disease was still confined to the liver. Jaundice has been a variable symptom and its presence or absence, probably is a matter of the location of a lesion. If a nodule compresses the hepatic duct, one may expect jaundice.

The paucity of cases leaves much to be desired clinically, but pathologically the reports, if analyzed, show remarkable consistency and leave little doubt of the nature of the disease.

The recent utilization of thorium dioxide as a liver stain in roentgen studies suggests its use in this disease. In the case here reported it was felt that the illness of the patient forbade its use, especially when thorium dioxide sol has hardly passed its probationary period as a diagnostic agent. I entertain the hope that it will prove very helpful.

1801 Eye Street N.W.

ECTOPIC SPLEEN

ARTHUR W. HOAGLUND, M.D., MINNEAPOLIS

This case is deemed of interest for the three following reasons: First, it is one of true extraperitoneal spleen; second, the original diagnosis was wrong, and, third, a more accurate interpretation of the original complaint may have led to the correct diagnosis. The major symptoms were entirely relieved by removal of the tumor.

A woman, aged 57, appeared for examination complaining of pain in the right leg. General physical examination gave negative results. There was no swelling, circulatory change, tenderness or any sign of abnormality of the right leg or of the groin. Pelvic examination revealed a tumor which felt hard. It seemed to be fixed in the right broad ligament, to extend into the flare of the pelvis and to originate from the uterus. The diagnosis was intraligamentous fibroid tumor. At laparotomy it was found that the uterus and the adnexa were normal and that the hard mass lay outside the peritoneum in the lateral hollow of the pelvis. The peritoneum was resected back, and further exploration revealed the tumor to be pierced by the external iliac artery. It was deemed inadvisable to attempt further dissection from within the pelvis, and the abdomen was closed. One week later an incision was made in the groin, and extraperitoneal dissection of the growth was accomplished. It was firm and encapsulated, 5 inches (12.7 cm.) long and 3 inches (7.6 cm.) thick, about the shape of a kidney, with a small notchlike nubbins that had wrapped itself completely around the external iliac artery and the femoral nerve. As this nubbins was shelled out, a definite constriction was visualized about the artery, and the pulsation in the femoral artery was definitely increased. The tumor was examined by Dr. Bell, professor of pathology at the University of Minnesota, and was diagnosed as spleen.

The pain in the leg was immediately relieved and the patient made an uneventful recovery. She has had no recurrence of symptoms.

SUMMARY

An extraperitoneal pelvic tumor manifested itself only by pain in the leg.

An incorrect diagnosis of intraligamentous fibroid growth was made.

At operation it was found that the tumor was wrapped around the external iliac artery and the femoral nerve.

The patient obtained complete relief after removal of the growth.

The tumor proved to be an aberrant extraperitoneal spleen.

74 South Ninth Street.

POSSIBLE PHENOLPHTHALEIN POISONING

WALDO E. NELSON, M.D., CINCINNATI

Ocasional untoward results have been reported following the use of various proprietary laxatives that supposedly contain phenolphthalein as the active ingredient. In many instances the disturbance has been chronic in nature and has followed prolonged administration. Cleaves¹ reports a fatal instance in a boy, aged 10 years, apparently due to the ingestion of a proprietary laxative preparation. The following case, with central nervous involvement, is presented as possibly due to excessive ingestion of a proprietary laxative:

A white boy, aged 3 years, admitted to the Children's Hospital, Dec. 25, 1932, had been ill following a heavy meal, November 24. The physician in attendance at that time suspected that the child had "tuberculosis." According to the grandmother, the child was not acutely ill at this time and was not confined to bed. November 29, he chewed and swallowed a large number (probably nineteen) of "gum laxative tablets." Following this, there was for a period of two days profuse diarrhea, some of the stools containing blood. Subsequently the child was troubled with constipation, vomited frequently, and was drowsy and unable to stand.

At the time of admission to the Children's Hospital the boy was in a semicomatose state; a bilateral internal strabismus was present; the neck was rigid; there was a positive Kernig sign bilaterally; a distinct tache cérébrale was obtained; both patellar reflexes were hyperactive, and the Babinski reflex and ankle clonus were absent. There was no evidence of otitis media. The urine contained a trace of albumin as well as a few pus cells and granular casts. The urine was normal on reexamination six days later. The spinal fluid was clear and contained 50 cells per cubic millimeter. The hemoglobin was 7.5 Gm. per hundred cubic centimeters; the red cell count, 4,700,000 per cubic millimeter; the white count, 10,200, with 75 per cent neutrophils. The Wassermann reaction was negative, as was the tuberculin reaction with 1 mg. of tuberculin. Roentgenograms of the chest were negative. There was no evidence of lead poisoning discovered on the roentgenograms of the long bones, nor was there any lead line on the gums or stippling of the red cells.

At the time of admission the child presented the appearance of a chronic form of meningitis or meningo-encephalitis. Tuberculosis could not be considered as the etiologic factor in view of the negative tuberculin test, the failure to find evidence of tuberculosis on the roentgenograms, the absence of tubercle bacilli in the spinal fluid, and the subsequent course of the case.

Improvement was slow, neurologic symptoms gradually disappearing and mentality returning to normal. March 13, 1933, three and a half months after the onset of symptoms, examination revealed no evidence of neurologic involvement except a questionable facial weakness.

The symptoms presented may perhaps be accounted for on the basis of the possible harmful effect of the medication. However, the indefinite illness of a few days prior to the ingestion of the laxative might have been the etiologic factor in producing an encephalitis.

Although it is not proved that the laxative was the causative or even the contributing agent, the danger of marketing laxatives as candy or gum, which children may use as simple confections, makes it seem desirable to report the case.

ABSCESS OF THE THYROID GLAND

ALLEN H. MOORE, M.D., DOYLESTOWN, PA.

Abscess of the thyroid gland is rarely primary; metastatic in character, it usually follows one of the acute infectious diseases, more commonly pneumonia, tonsillitis or cervical adenitis. In all the accounts, suppuration of the thyroid is considered rare, thyroiditis in general occurring in from 1 to 0.25 per cent in operative material and observed clinical cases.

There is no age at which the disease cannot be found. According to Miggend, women are more susceptible than men. Meara and MacGregor¹ reported a case in a 3½ year old child with a suppurating thyroid. Wilkins² reported a case occurring at the age of 74. The usual age of incidence is from 20 to 45 years.

When suppuration of the thyroid develops, the abscesses are as a rule multiple, each, however, tending to break through the adjoining soft tissues, thus leading to confluence and to rupture through the skin or purulent infiltration of the surrounding structures.

The common primary manifestations exhibited in abscess of the thyroid gland are signs of inflammation, redness, swelling and edema of the overlying tissues in the median line. Beilby³ believes that the pathognomonic sign is the stony hardness of the gland elicited on palpation; no other condition except carcinoma gives a similar feeling. The disease may be mistaken for a sarcoma, as in a case reported by Bonney,⁴ which was afterward found to be an abscess and opened. It may also be confused with glossitis, abscess at the base of the tongue, laryngitis, esophageal abscess and perichondritis of the larynx and neck muscles.

In many of the cases of thyroid abscess, limitation of elevation of the chin and depression of the chin on the sternum when swallowing are prominent signs. These two signs, I believe, are of great significance in the differentiation of the disease. They are brought about by the action of the sternohyoid, sternothyroid and omohyoid muscles on the abscess beneath them. One may easily perceive how pain may result from tightening of these muscles, and how tightening as the result of swallowing may be prevented by depression of the chin on the sternum.

The case that is the subject of the present report was noteworthy because of its indirect mode of onset, its apparent primary invasion, the failure in diagnosis and the fatal ending.

H. N. A., a youth, aged 20, a student at the National Farm School, admitted to the school infirmary in my service, at the time of admission complained of a subclavicular pain in the midclavicular line of the left side of the chest. On admission his temperature and pulse were normal. Since he was a member of the school football squad, it was first thought that he was suffering from a consequent injury. He stated frankly that he had not received an injury on the field or at any time during the routine of his usual work at the institution. His only complaint was that of pain in the left side of the chest. He had suffered from this pain for about ten days before being admitted to the school infirmary. There was a circumscribed area of tenderness 6 cm. in diameter exactly where he complained of pain. This area was slightly reddened and somewhat edematous. It was of a doughy consistency. There were a few crepitant râles audible at the apex of the left lung. There were no friction or other adventitious sounds. The right lung presented nothing abnormal.

The eyes evidenced a marked exophthalmos. The history revealed this as a congenital condition. The pupils were equal and reacted normally to light and in accommodation. There was no photophobia. The throat was dry and congested. The tonsils did not show any acute infection. There was no rigidity of the neck, nor was pain experienced while the head was in motion. The patellar reflex was normal. There was no Kernig and no Babinski reflex. The abdomen was soft, and the edge of the liver was easily palpable. The spleen was not palpable.

The day following admission to the Farm School Infirmary, the patient showed a marked change for the worse. The temperature was then 102 F. and the pulse 110. Blood pressure

was 118 systolic and 65 diastolic. The face was flushed and the patient showed definite signs of a rapidly oncoming toxemia. He was anxious and complained more of the pain in the left side of the chest. The area of tenderness extended to the clavicle. There was no redness, edema, fluctuation, pain or tenderness over the region of the thyroid gland. Pain could not be elicited even on deep pressure over the thyroid. The patient's condition grew progressively worse and he was later admitted to the Jewish Hospital in Philadelphia. On admission, his temperature had risen to 103.3 and the pulse to 120. He was very restless and toxic, and he complained of a sore throat and a severe headache. Later in the day there was a chill of considerable severity. The second day after admission the tenderness extended to the left side of the neck, rotation of the head causing exquisite pain. A lumbar puncture was negative. Roentgen examination of the chest and neck was negative.

There was a tentative diagnosis of superior mediastinitis of undetermined origin. The next symptom that appeared was vomiting. The pulse became still more rapid. Puncture of the chest, neck and thyroid gland failed to reveal the presence of pus. October 3, nearly two weeks after the onset of the disease, the swelling in the neck subsided slightly but the tenderness was still present. The temperature rose to 106.3 and the pulse to 170. The patient became cyanotic. The respirations were rapid and coma ensued, death following shortly after coma had supervened. A postmortem examination revealed a large, deep-seated abscess of the thyroid gland.

SUMMARY

1. The gradual onset of a subclavicular pain with an upward extension of the area of tenderness was unusual.
 2. The characteristic signs of inflammation with swelling in the midline of the neck in the region of the thyroid were not present until late in the progress of the disease.
 3. On account of the proximity of the cervical fascia and its relation to the mediastinum, early incision in such cases is most important for the preservation of life.
 4. The abscess was apparently of primary origin.
- 106 East State Street.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
H. A. CARTER, Secretary.

**BURDICK DIATHERMY MACHINE
MODEL D-2 ACCEPTABLE**

The Burdick Corporation, Milton, Wis., submitted a model D-2 Diathermy Machine to the Council for investigation and report. The manufacturer claims that the unit provides sufficient capacity for full range medical and surgical diathermy practice commonly encountered in office and institution. The firm agrees to market the product in accordance with the Council's published statement, entitled "Diathermy: A Preliminary Statement to Acceptance of Diathermy Apparatus."

In the manufacturer's opinion, the Model D-2 Diathermy Machine produces sufficient electrical energy to provide heat for the treatment of the indications mentioned in the Handbook of Physical Therapy or other Council accepted medical literature. For surgical work, the concern claims that the Model D-2 Diathermy Machine generates enough electrical power for use in electrocoagulation of tonsils and in certain forms of surgery when indicated. The apparatus is arranged for the production of Oudin current, a high-frequency current of higher voltage than the high frequency currents used for ordinary diathermy treatments. Oudin current, the company writes, is recommended for desiccation.

The Burdick Diathermy Machine Model D-2 is mounted in a cabinet made of genuine walnut. The top frame is solid walnut and the remaining cabinet heavily veneered. The size of the diathermy unit proper is 23 inches wide, 16¾ inches deep and 11½ inches high at the top of the panel board. The spark gap assembly projects a few inches above. The unit may

1. Meara, F. S., and MacGregor, R. S.: Arch. Pediat. 23: 591 (Aug.) 1906.

2. Wilkins, A. G.: Brit. M. J. 2: 1005, 1904.

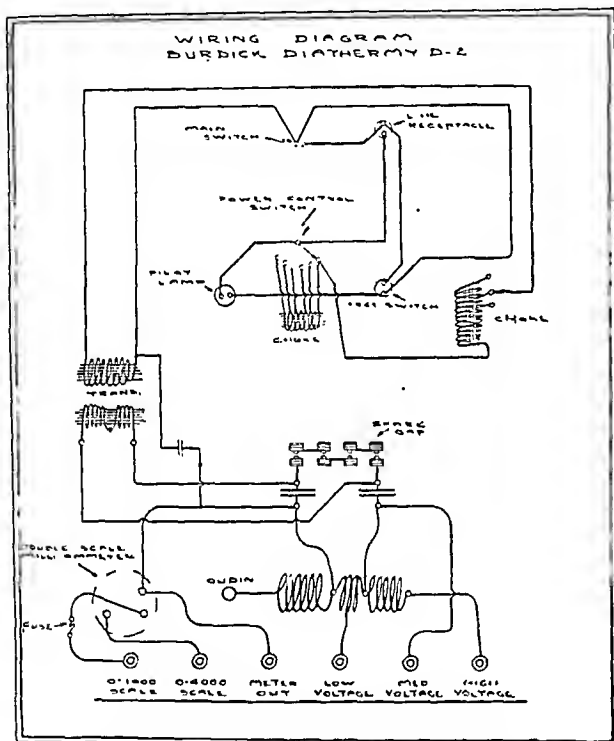

3. Beilby, G. E.: New York State J. Med. 19: 173 (July) 1919.

4. Bonney, C. W.: Lancet 2: 155 (July) 1911.

be mounted on a mobile stand or cabinet especially built for the purpose.

Three connections are provided to permit proper operation on any line voltage. The taps are marked 105, 115 and 125 volts. This provides for maximum output on low voltage line and also aids in protecting the apparatus against burnout on high voltage line. The device is designed to operate on 110-125 volt, 60 cycle alternating current. In case direct current is the only source, the physician is obliged to purchase a rectifier at an additional cost. The panel board is made of bakelite with gloss finish. Descriptive lettering is all hand engraved. All controls and switches are said to be located for maximum convenience. The Oudin current ball terminal is concealed to prevent contact with the operator's hand or arm. A foot switch receptacle is provided.

There is a six point power control operated by a specially designed positive stop switch. The position of the switch handle indicates the setting of power control even when the numbers are not readily visible to the operator from a distance.

Schematic diagram of electrical connections of Burdick Diathermy Machine Model D-2.

The spark gap is built with eight three-eighths inch tungsten points equipped with both master and individual gap controls. Turned solid metal radiators provide thermal conductivity. The spark gap is shielded with an ornamental guard.

The transformer is of the high voltage type, well insulated, and is said to be capable of prolonged operation without overheating. It produces 5,000 or more volts at full output. The condensers are built of mica and copper plates and built in special radiator type aluminum mountings. The resonator is grounded on bakelite grooved tubing. The patient circuit is grounded free from the line. The milliammeter is plug-in thermocouple type with protective fuse concealed by the meter. The upper scale reads from 0 to 6,000, the lower scale from 0 to 1,500. A pilot lamp with filtered light is provided. It shows red only when the current is on. All contacts or current carrying parts are concealed, thus tending to prevent accidental shock from the machine.

The accompanying diagram shows schematically the electrical connections of the apparatus.

The Council on Physical Therapy declares the Burdick Diathermy Machine Model D-2 eligible for inclusion in its list of accepted devices for one year.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ERYSIPELAS STREPTOCOCCUS ANTITOXIN (See New and Nonofficial Remedies, 1933, p. 363).

Parke, Davis & Co., Detroit.

Erysipelas Streptococcus Antitoxin Refused and Concentrated—P. D. & Co. (See New and Nonofficial Remedies, 1933, p. 364).—Also marketed in packages of one piston syringe containing 20 cc.

SAL ETHYL CARBONATE.—The carbonic acid ester of ethyl salicylate.—Salicylic ethyl ester carbonate.— $O:C(OC_2H_5.COOC_2H_5)_2$.

Actions and Uses.—Sal-ethyl carbonate provides the antipyretic and analgesic effects of the salicylates. It is relatively insoluble in water and in the acid secretions of the stomach, whereby the disagreeable taste and local gastric symptoms of the soluble salicylates are practically avoided. For cases requiring a rapid analgesic and antipyretic effect rather than salicylate saturation, tablets sal-ethyl carbonate with amidopyrine are supplied.

Dosage.—Sal-ethyl carbonate and tablets sal-ethyl carbonate with amidopyrine may be given in dosages ranging from 0.3 to 1 Gm. (5 to 15 grains), three or four times daily, according to the individual requirements.

Manufactured by Parke, Davis & Co., Detroit. No U. S. patent. U. S. trademark 92,115.

Compressed Tablets Sal-Ethyl Carbonate 5 gms.

Compressed Tablets Sal-Ethyl Carbonate with Amidopyrine: Each tablet contains sal-ethyl carbonate 0.23 Gm. (3½ grains) and amidopyrine 0.1 Gm. (1½ grains).

Tablet Triturates Sal-Ethyl Carbonate 1 gr.

Sal-ethyl carbonate occurs as white, odorless and tasteless crystals. It is almost insoluble in water and diluted hydrochloric acid. It is slightly soluble in ether and alcohol but readily soluble in chloroform and acetone. It melts between 96 and 99 C.

Transfer about 2 Gm. of sal-ethyl carbonate to a test tube, add 5 cc. of half normal alcoholic potassium hydroxide and heat on the steam bath for five minutes; the product dissolves, followed by the formation of a precipitate; cool, decant the supernatant liquid, add 6 per cent acetic acid to the precipitate; it effervesces; add an equal volume of water to the decanted liquid; a colorless oil separates that has the odor of ethyl salicylate. Transfer about 1 Gm. of sal-ethyl carbonate to an Erlenmeyer flask, add 20 cc. of normal sodium hydroxide, 20 cc. of alcohol and boil under a reflux condenser for thirty minutes; cool, acidify the solution by addition of diluted sulphuric acid; extract the solution with 20 cc. of ether, filter the ether, evaporate to dryness; the residue responds to qualitative tests for salicylic acid.

Dissolve about 0.5 Gm. of sal-ethyl carbonate in 10 cc. of sulphuric acid: the solution remains colorless for five minutes (*readily carbonizable substances*). Transfer about 0.5 Gm. of sal-ethyl carbonate to a test tube, add 10 cc. of water and a few drops of ferric chloride solution: no blue color develops (*salicylic acid*).

Transfer about 1 Gm. of sal-ethyl carbonate, accurately weighed, to an Erlenmeyer flask, add 40 cc. of half-normal alcoholic potassium hydroxide, boil under a reflux condenser on the steam bath for three hours, wash the condenser and add the washings to the flask, remove the alcohol by evaporating to about one-third the volume, adding 50 cc. of water and evaporating to about 15 cc., transfer the solution to a 250 cc. volumetric flask, make up to volume by addition of water. Transfer a 25 cc. aliquot to an Erlenmeyer flask and test the solution according to the method for total salicylate described in the A. O. A. C. Manual, third edition, page 446, Iodine Method, paragraph 24: the weight of the tetraiodophenylene quinone multiplied by 0.5208 and by the aliquot factor is equivalent to not less than 98.5 per cent nor more than 100.5 per cent of the sample taken. Transfer about 1 Gm. of sal-ethyl carbonate, accurately weighed, to a tared weighing bottle; heat in an oven at 100 C. for one hour; cool in a desiccator and weigh: the loss in weight is not greater than 1 per cent. Transfer about 0.5 Gm. of sal-ethyl carbonate, accurately weighed, to a platinum dish and ignite: the ash is not more than 0.02 per cent.

PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1933, p. 58).

The following dosage forms have been accepted:

Sterile Ampoules Procaine Hydrochloride Crystals For Spinal Anesthesia, 100 mg.

Sterile Ampoules Procaine Hydrochloride Crystals For Spinal Anesthesia, 120 mg.

Sterile Ampoules Procaine Hydrochloride Crystals For Spinal Anesthesia, 150 mg.

Sterile Ampoules Procaine Hydrochloride Crystals For Spinal Anesthesia, 200 mg.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

EUPHYDIGITAL NOT ACCEPTABLE
FOR N. N. R.

Euphydigital (Byk-Guldenwerke, Berlin, Germany; Byk, Inc., New York, American agents; Adolphe Hurst & Co., Inc., New York, General Distributors) is said to be a combination of Metaphyllin and digitalis. Each tablet is stated to contain 0.1 Gm. of Metaphyllin and 0.1 Gm. of powdered digitalis leaf ("150 frog doses"). Each suppository is said to contain 0.2 Gm. of Metaphyllin and 0.15 Gm. of powdered digitalis leaf ("225 frog doses"). One or two tablets are to be taken three times daily, or two or three suppositories daily. Metaphyllin (formerly called Euphyllin) is said to be a combination of approximately 78 per cent of theophylline with ethylenediamine, having the advantage of being more soluble than theophylline.

Advertising for Euphydigital received by a physician in April, 1932, states that "the action of digitalis can be considerably increased by the simultaneous administration of Metaphyllin." This is a remarkable statement in view of the fact that up to about 9 grains of digitalis daily is recommended in the form of Euphydigital. This advertising reiterates certain of the claims for Metaphyllin which the Council could not accept. Thus, it is stated, "Metaphyllin being a readily soluble combination of Theophylline, possesses in a specially high degree the characteristic, that besides effecting an increased excretion of water it also eliminates urea, common salt and extraneous substances. . . . Of particular importance is its action—which greatly surpasses that of any of the purin bodies—as a vasodilator. By reason of its dilatant action on the blood-vessels Metaphyllin has gained an ever-increasing significance as a cardiac. . . . An advantage of Metaphyllin of the greatest consequence is that the constrictive action which is effected on the coronary vessels by digitalis bodies is compensated by the vaso-dilatant action of Metaphyllin; and this is of special importance where anginous conditions are in question." Among the great advantages claimed for Euphydigital are: "By reason of the vaso-dilatant action of Metaphyllin, particularly that on the coronary vessels, Euphydigital may also be administered in coronary sclerosis and angina pectoris. . . . Euphydigital may also be given in cases of heart decompensation with raised bloodpressure for combating the insufficiency symptoms, as the bloodpressure-decreasing characteristic of the Metaphyllin constituents forms a safeguard against any further rise in the bloodpressure by means of the digitalis."

From the foregoing it is concluded, in the advertising circular, that "Euphydigital is thus not only indicated in all such cases where digitalis is employed, but by means of this preparation it has become possible to include in heart and circulatory therapy a range of disease conditions in which the necessary digitalis treatment in view of its by-effects was prohibited or had to be carried out with the utmost precaution." This is distinctly misleading, and even dangerous, because it implies that Metaphyllin permits of the use of digitalis in the treatment of disease conditions without the utmost precaution. It is well known that patients suffering with cardiac disease and nephritis often require both digitalis and one of the purines, such as theobromine or theophylline, and it is considered in the last degree irrational to use a mixture of digitalis with any other substance. Large doses of digitalis are commonly given in the beginning of treatment and the dose is greatly reduced as soon as the heart is digitalized. Similarly, one must determine the dose of the purine body from time to time, dependent on a variety of conditions, and this is quite impossible when one uses a mixture of the two substances. There is no evidence that Metaphyllin possesses the capacity for causing marked coronary dilatation in cases in which it is imperatively needed; and it is misleading to state that digitalis constricts the coronaries, because there is no evidence that digitalis has such action, especially when used in the presence of coronary sclerosis.

The Council declared Euphydigital unacceptable for New and Nonofficial Remedies because it is an irrational mixture of digitalis and a theophylline preparation marketed under an uninforming, proprietary name, with exaggerated and unwarranted claims for its therapeutic value.

Committee on Foods

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

IRRADIATED VITAMIN D PASTEURIZED
MILK ADVERTISING OF BORDEN'S
FARM PRODUCTS COMPANY
OF MICHIGAN

Distributor.—Borden's Farm Products Company of Michigan, Detroit (subsidiary of the Borden Company, New York).

Description.—Advertising for bottled pasteurized vitamin D milk irradiated by Steenbock Process (patent No. 1680818).

Preparation.—The milk complies with the analytic and bacteriologic requirements specified by the laws of the state of Michigan and the city of Detroit or other municipalities in which it is distributed.

The milk is pasteurized by the standard procedure (holding method, thirty minutes at 61 C.), is exposed in a thin moving film for sixteen seconds to ultraviolet rays from a battery of carbon arc lamps and is automatically bottled. The bottled milk complies with the requirements of the state of Michigan and of health departments having jurisdiction over its production, processing, bottling and distribution. The method of irradiation and the equipment are under scientific control.

Vitamins.—Clinical investigation shows this irradiated milk when used in proper quantities to be a reliable antirachitic agent protecting all infants excepting those prematurely born.

Claims of Manufacturer.—An irradiated antirachitic pasteurized milk having the natural unaltered flavor and other food values of standard pasteurized milk.

CERTI-TEST FLOUR (BLEACHED)

Manufacturer.—The Robinson Milling Company, Salina, Kan.

Description.—A "straight" hard winter wheat flour; bleached.

Manufacturer.—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, and bleached with nitrogen trichloride (one-seventh ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (one-half ounce per 196 pounds).

Claims of Manufacturer.—The flour is for bread baking.

ROTH'S WHITE HEARTH BREAD
(CORNMEAL TOPPING)

Manufacturer.—The A. Roth Baking Company, Newport, Ky.

Description.—A white hearth bread with cornmeal topping made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817); prepared from patent flour, water, sucrose, yeast, salt, malt syrup, lard and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Claims of Manufacturer.—Conforms to the United States Department of Agriculture definition and standard for white bread.

K-K AMBER TABLE SYRUP (CORN SYRUP
FLAVORED WITH REFINERS' SYRUP)

Packer.—Wheeler-Barnes Company, Minneapolis.

Distributor.—Andrew Kuehn Company, Sioux Falls, S. D.

Description.—Table syrup; corn syrup base (85 per cent) with refiners' syrup (15 per cent); the same as Golden Oak Brand Amber Syrup (85 per cent corn syrup, 15 per cent refiners' syrup), described in THE JOURNAL, Dec. 3, 1932, page 1948.

**LARSEN'S STRAINED BEETS UNSEASONED—
READY FOR USE**

Manufacturer.—The Larsen Company, Green Bay, Wis.

Description.—Sieved beets prepared by efficient methods for retention in high degree of the natural mineral and vitamin values of the raw beets. No added sugar or salt.

Manufacture.—Freshly harvested beets are sorted, washed, mechanically peeled, inspected for removal of undesirable material, steamed until soft and puréed in an atmosphere of steam in a paddle type puréeing machine of monel metal with a bronze rotor. The puréed beets are brought to the desired consistency with a small amount of water, heated to 82 C. in a closed kettle and automatically filled into washed cans, which are sealed and processed for thirty minutes at 116 C.

Analysis (submitted by manufacturer).—

| | per cent |
|---|----------|
| Moisture | 89.7 |
| Total solids | 10.3 |
| Ash | 0.5 |
| Salt (NaCl) | 0.02 |
| Fat (ether extract) | 0.1 |
| Protein (N X 6.25) | 1.1 |
| Crude fiber | 0.5 |
| Carbohydrates other than crude fiber (by difference)... | 8.1 |

Calories.—0.4 per gram; 11 per ounce.

Vitamins and Claims of Manufacturer.—See Larsen's Strained Tomatoes Unseasoned—Ready for Use (THE JOURNAL, July 1, 1933, p. 35).

1. MINNEAPOLIS BEST FLOUR (BLEACHED)
2. COMMANDER FLOUR (BLEACHED)
3. BIG DIAMOND FLOUR (BLEACHED)
4. BEST ON RECORD FLOUR (BLEACHED)
5. SUNSHINE FLOUR (BLEACHED)

Distributors.—

1. Minneapolis Milling Company.
2. Commander Milling Company.
3. Big Diamond Mills Company.
4. Empire Milling Company.
5. Stokes Milling Company.

Subsidiaries of the Commander-Larabee Corporation, Minneapolis.

Description.—Hard spring wheat "straight" flour; bleached.

Manufacture.—Selected hard spring wheat is cleaned, washed, tempered, milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with one twenty-fifth ounce of nitrogen trichloride and with a mixture of three-fourths ounce of benzoyl peroxide and calcium phosphate per barrel.

Claims of Manufacturer.—For commercial bakeshop and family use.

**SPANG'S GOLDEN GUERNSEY
WHOLE MILK LOAF**

Manufacturer.—Spang's Home Bake Bakeries, Cleveland and Lorain, Ohio.

Description.—A milk bread made by the straight dough method (method described in THE JOURNAL, March 12, p. 889), prepared from flour, Guernsey whole milk, sucrose, yeast, salt and diastatic malt extract.

Analysis (submitted by manufacturer).—

| | per cent |
|---|----------|
| Moisture (entire loaf) | 37.5 |
| Ash | 1.9 |
| Fat | 2.9 |
| Protein (N X 6.25) | 10.0 |
| Crude fiber | 0.2 |
| Carbohydrates other than crude fiber (by difference) .. | 47.5 |

Calories.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A milk bread conforming to the respective United States Department of Agriculture Definition and Standard. Guernsey milk is used.

BUTTER-CUP EVAPORATED MILK

Packer.—Dean Milk Company, Chicago.

Distributor.—R. A. McKee Corporation, New York.

Description.—Unsweetened, sterilized evaporated milk; the same as Dean's Quality Evaporated Milk (THE JOURNAL, Aug. 6, 1932, p. 477).

MOTHER'S JUMBO BREAD

Manufacturer.—M. Erickson Bakery Company, Inc., La Crosse, Wis.

Description.—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817); prepared from patent flour, water, sweetened skim condensed milk, lard, sucrose, salt, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Claims of Manufacturer.—Conforms to the United States Department of Agriculture definition and standard for white bread.

SUNSHINE SELF-RISING FLOUR (BLEACHED)

Manufacturer.—Saxony Mills, St. Louis.

Description.—This is the same as the accepted Arbitrator Patent Flour, Self Rising (Bleached) (THE JOURNAL, Jan. 14, 1933, page 117) containing soft winter wheat patent flour, calcium acid phosphate, baking soda and salt.

REPORTS OF THE COMMITTEE

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
RAYMOND HERTWIG, Secretary.

NOT ACCEPTABLE**RALSTON WHEAT OATA (NEW NAME)****NEW OATA (FORMER NAME)**

The Ralston Purina Company, St. Louis, has changed the name for its previously accepted "New Oata," a mixture of rolled oats and wheat, much the greater proportion of which is oats, to "Ralston Wheat Oata" without discussing the name change with the Committee. The new name "Wheat Oata," by giving first place to wheat, emphasizes the wheat content over that of the oats, thereby connoting that the wheat is in greater proportion than is the oats, which is contrary to fact, the oats being in much the greater proportion. The name "Wheat Oata," therefore, is misinformative and misleading. An appropriate descriptive name for this product would give first place to the predominant ingredient "oats." The label states, "This unusual porridge combines the distinctive flavors and the abundant health-building qualities of whole rolled wheat and whole rolled oats." Wheat and oats do not have "health building qualities" any more than do other common foods; no food provides or assures health. A complete diet adequate in all food essentials is necessary for health, but health depends on many other factors than nutrition.

The company was advised of the Committee's report but has not expressed itself as willing to change the inappropriate name and label statement. The Committee's acceptance is being withdrawn and the product will therefore no longer be listed among the Committee's accepted foods.

ACCEPTANCE WITHDRAWN

SAC-A-RIN BRAND APRICOTS, BARTLETT PEARS, MUSCAT GRAPES, ROYAL ANNE CHERRIES, TIDBITS HAWAIIAN PINEAPPLE, SEEDLESS GRAPES, YELLOW CLING PEACHES AND WHOLE RIPE KADOTA FIGS (PACKED WITHOUT ADDED SUGAR OR SALT)

Manufacturer.—Kings County Packing Company, Ltd., Oakland, Calif.

Discussion.—The manufacturer has not provided the complete list of the ingredients and quantities thereof, chemical analysis, specifications or description of materials used in its preparation, and description of manufacture being required for all accepted foods by the Committee's present Rules and Regulations. The previous acceptance of the Council on Pharmacy and Chemistry and later of the Committee on Foods is therefore being withdrawn; the products will no longer be listed among the Committee's accepted foods.

SATURDAY, JULY 8, 1933

POISONOUS INSECTICIDES AND PLANT SPRAYS

For every crop that is planted, nature provides several outlets. As is pointed out in the introduction to a symposium on insecticides¹ in *Industrial and Engineering Chemistry*, the first claimant is the human being who plants the crop, takes care of it and rightly expects to garner the fruits of his labor. The second claimant is a group of insects and fungi which also live on crops and which may at any time take advantage of the absence or deficiencies of the human planter in order to maintain its own life. Since the beginning of mankind on this earth, a battle has been waged constantly between these two types of claimants. Before the coming of modern chemical science it seemed likely that the insects would eventually win. Today, however, the development of the new science of plant husbandry has thrown the advantage with the human being.

Unfortunately, every change made in conditions of living brings about hazards that may not be considered at the time the changes are made. The motor car is a great advance but today probably is producing as many cases of illness and death as any recognized disease. Modern methods of living in apartment houses and of taking pleasure in groups of thousands have their advantages, but associated with these is the increased facility of transmission of respiratory disease. Previous to 1860, sprays of nicotine, tobacco dust and hellebore were chiefly used in combating the insects that live on plants. In that year paris green was introduced to control the Colorado potato beetle, and since that time a considerable number of arsenic-containing mixtures and compounds have been added to the farmer's armamentarium. Lead is used in many different forms. The possibility of hazards from arsenic, lead and similar types of substances has stimulated a search for less poisonous spray material. In the case of fruits, poisonous residues from insecticides may be removed by thorough washing, though this sometimes requires the employment of such strong agents as hydrochloric

acid. With vegetables there must be means of controlling the amount of insecticide applied, and also means for removal of residues by washing or stripping. In the case of some vegetables, such as asparagus, none of the methods now available seem certainly safe. In the symposium already referred to, the contributing authorities mention particularly the experiments with the application of chemical solvents, the cleaning of fruit by wiping and by washing, and similar methods.

In his contribution to the symposium, Dr. White² of the Food and Drug Administration indicates that federal jurisdiction cannot reach poisonous food within the borders of the individual states and that the responsibility of shipping wholesome food rests wholly on the shipper and the receiver. The Food and Drug Administration may seize food shipped in interstate commerce if it contains spray residues of arsenic, lead or fluorine in such amounts as to be found beyond a reasonable doubt dangerous to human health.

In the same symposium, Myers and his associates³ in New York point out that twenty-nine million pounds of calcium arsenate and twenty-nine million pounds of lead arsenate were employed for insecticide purposes in the year 1929 in this country. They endeavored to determine the extent of the hazard to human health and are inclined to believe that the presence of arsenic and lead in 80 per cent of human beings suffering with alopecia may indicate a causative relationship. They are convinced that present methods of washing and removing spray residue are inefficient and inexact, particularly as applied to compounds containing lead. The use of various chemicals such as selenium, thiocyanates and rotenone is discussed by chemists who gave special attention to these products. Incidentally, the development of plants for the grinding of derris root and other rotenone-bearing insecticides raises hazards for the workers in the plants who breathe the dusts and thereafter develop numbness of the lips and irritations of the throat.

Throughout the world, various commissions have considered the minimum amount of lead and arsenic remaining on fruits that have been sprayed, and in April, 1933, the Food and Drug Administration announced that 0.014 grain per pound, or 2 parts of lead (Pb) per million would be permitted, and that the arsenic would remain at 0.01 grain per pound, or 1.4 parts per million as As_2O_3 . These figures agree with those set up by a British royal commission⁴ dealing with a similar problem. The United States Department of Agriculture has constantly recommended acid washing methods; it has had difficulty in getting the compliance of farmers and fruit growers, who insist that there is no danger whatever from these metallic poisons as used on fruits and demand records of cases of poi-

1. Symposium on Insecticides, *Indust. & Engin. Chem.*, 25: 616 (June) 1933.

4. Report and Minutes of Evidence on Arsenical Poisoning from Beer and Other Articles, Eye & Spottiswoode, 1903.

soning or death attributable to the metallic residues. They rely, of course, on the fact that the poisoning is not acute but apt to be chronic, because no large amounts of poison are likely to be taken at one time by the consumer of the fruit. Moreover, growers do not appreciate the danger of cumulative chronic poisoning. Physicians living in areas devoted largely to fruit growing seem to be in support of the orchardists rather than of the Food and Drug Administration. For a while, attempts were made to substitute fluorine compounds for arsenicals but there is evidence which seems to establish the deleterious character of the fluorine compounds recommended.

In view of the available evidence, the consumer of today need not fear acute poisoning the next time he eats an apple, an orange, cabbage, lettuce or celery, or any of the other fruits or vegetables commonly sprayed or dusted with the insecticides that have been mentioned. It is well to know, however, that a hazard does exist although its exact extent is not yet quite measurable. In the interests of safety, not only from contamination by food handlers with infectious organisms but also because of the possible dangers from the metallic poisons that have been mentioned, it is well for the user to wash thoroughly and to cleanse such materials before putting them on the table in either the raw or the cooked form, and perhaps to strip and destroy the outer layers of lettuce, cabbage and similar vegetables that lend themselves easily to such manipulations. In the meantime, much excellent research is being carried on both by the government and by the industries involved to eliminate as far as possible these hazards to human health and life.

LATENT AVITAMINOSIS

The concept of deficiency diseases, in contrast to maladies that owe their origin to some positive factor such as infections or parasitic organisms in the body, is comparatively new; its varied implications are not yet clearly understood. Obviously, such manifestations as outspoken scurvy, florid rickets, severe beriberi and pronounced xerophthalmia no longer call for debate with respect to the genesis of the conspicuous symptoms. The clear recognition of the causes has served to hasten the prevention as well as the cure of the disorders. It may be expected that a large group of formerly disconcerting maladies will become rarities in parts of the world where they were at one time dreaded and managed at best with great difficulty.

There are, however, insidious features of incipient avitaminosis that are not so readily appreciated. The time has arrived when more serious consideration must be given to them; when the possibilities of their incidental and less obvious effects must be taken into account in presumably far more patients than is at present assumed to be likely. As a recent writer has

remarked,¹ since the cause of most deficiency diseases has been established, and since an efficacious and easily available cure has been found to exist in the observance of what is now regarded as a protective and well balanced diet, there is a strong tendency to regard these diseases as belonging to the bygone prescientific ages. This, together with the fact that ill health may be produced by deficiency of a food factor in amounts much smaller than those necessary to create the typical full-blown picture associated with its lack, explains why the deficiency syndromes are more common than their diagnosis. It is to be expected, therefore, that deficiency syndromes may occur in persons existing for any considerable length of time on a restricted diet, either therapeutic or voluntary, or as a result of dietary eccentricities.

"Latent" scurvy has long been under consideration by practitioners; it was contrasted with the so-called inveterate scurvy of the older writers. In his classic treatise on "Scurvy: Past and Present," A. F. Hess wrote that the acute, florid type presents a striking picture but must not be regarded as the common form of the disorder. "If we are to diagnose infantile scurvy early," he wrote, "and not overlook its more subtle manifestations, the classic textbook description must be augmented by portrayals of types of the disorder which are less crude and more difficult to recognize—of 'subacute' and of 'latent' scurvy." Indeed, Hess stated in 1920 that the condition of latent scurvy is probably the commonest type of the disorder. This was written, it should be added, at a period when the use of antiscorbutics had not yet become as widespread or nearly universal as is now the case.

Latent scurvy is undoubtedly only a single instance of numerous single or multiple incipient or subacute avitaminoses. McLester,² in discussing general malnutrition, has noted that man's diet is seldom faulty in respect to one factor alone. When deficient, it usually exhibits several errors, and the resulting clinical picture is correspondingly obscure. To use the words of McCollum, faulty diet does not often produce sudden and graphic consequences; its results are slow, insidious and difficult of recognition. The physician is chiefly interested in nutritional failure not because of its relation to scurvy, beriberi or any other well defined disease but because it produces numberless vague, poorly defined states of ill health. To prevent nutritional failure, the diet should be considered as a whole, and all essentials, whether vitamin, protein or mineral, should be accorded equal importance. The relation which these bear to one another is also of significance, for that which is optimal under certain conditions may under other circumstances and in other combinations be faulty.

1. Dry, T. J.: Avitaminosis in Natives of Rhodesia, *Arch. Int. Med.* 51: 679 (May) 1933.

2. McLester, J. S.: *Nutrition and Diet in Health and Disease*, Philadelphia, W. B. Saunders Company, 1931.

Even today one can cite recorded instances of malaise among persons living in the "twilight zone" of good nutrition. Often it occurs in patients who have resorted to some extreme or restricted dietary regimen in order to combat a well defined disorder. This was noted in the treatment of gastric ulcer by Davidson³ several years ago. He remarked that, in the overwhelming enthusiasm for controlling obvious functional derangements by dietetic measures, the maintenance of the patient on a diet containing the necessary accessory food factors is often ignored. Diet prescriptions—and proscriptions—in the management of colitis undoubtedly often conduce to mild avitaminosis; and superimposed infections undoubtedly aggravate the situation.

Even amid readily available opportunities for protection against avitaminosis, nutritive disaster may arise through ignorance or the perversions due to customs and habits. An illuminating instance has lately been reported by Dry,¹ who was a medical officer in Rhodesia, South Africa, serving the Kaffirs employed in governmental enterprises that took these natives away from their natural habitats. The government rations were well selected. The important sources of vitamins were green vegetables, meat and beans (which are sprouted prior to cooking), but the native was as likely to discard these as he was to render them valueless by excessive cooking. Latent scurvy was common, as were carious teeth among natives afflicted with the disease, and this is of unusual interest, as the African aborigines are credited with as nearly perfect teeth as are possible to be found. As might be expected, the medical administration of familiar antiscorbutics was promptly effective. Dry reports that the demand for fresh fruits and vegetables could be met only by importation from considerable distances, since local production of sufficient quantities was not possible. Even so, the supplies were not inadequate. But the most serious obstacle was the unwillingness of the native to make use of such supplies, once procured. The savage, whose mind is warped by fear and superstition and who is blind to the consequences of depending solely on his traditional fare under circumstances so entirely different from his traditional mode of living, cannot be readily induced to comprehend either the nature of his illness or the means to rectify it. In comparing the group of patients treated by means of oral administration at the outset with the group treated by the intravenous method, one can definitely state that the rate of recovery was more rapid, as shown by the shorter period of hospitalization when the latter form of administration was adopted. The experience of Dry adds another to the many instances which indicate that chronic malnutrition leads to physical inferiority. It is the problem of the intelligent clinician to discover and correct the defects at the earliest moment. In planning an attack against the danger, it is well to bear

in mind the dictum of a recent writer:² "Why are some people undernourished? Inability to secure proper food, ignorance of the laws of nutrition, and capricious appetite—one or all of these causes are usually responsible. In America it is only under rare conditions of extreme poverty that the first cause is effective; the person who knows what to eat can, by dint of effort, usually obtain it. The second reason is the usual one; a failure to appreciate the value of milk, fruits and green vegetables, and phobias toward meat are common. Perverted taste plays a minor rôle. Education is the logical corrective measure."

THE PROTEIN INTAKE OF PRESCHOOL CHILDREN

The progress of the physiologic sciences has been relatively slow in their investigation of certain periods of early life. The problems of infant nutrition, for example, have scarcely attracted less attention than have those of adult life; but until recently the earlier stages of childhood have had comparative neglect from students of human well being. Some of the reasons for this seeming indifference toward our adolescent population lie in the difficulties of investigation. The infant is under complete personal control, owing to its inability to shift for itself. The school child has developed a degree of intelligence that makes its cooperation reasonably easy to secure in many scientific investigations. Within the intermediate age groups there are obvious difficulties of management under the ordinary routine of child life. The growing organization of preschool training in this country has, however, afforded new possibilities that are rapidly being utilized in the study of the child.

This is cogently exemplified in the extensive records of the White House Conference on Child Health and Protection.¹ Because of the difficulties involved in children in the measurement of the output of heat either directly or indirectly under conditions of normal activity, investigators have turned their attention to studies of intake instead, assuming that the potential energy taken in as food under specified conditions should indicate the amount required. In general, such studies fall into two types: balance experiments and dietary studies. To date, all the balance experiments that have been reported have added only relatively meager data that can be used for standards. Many of the studies, to be sure, were not made for this purpose and should not be criticized on this score.

This situation leaves the possibility of dietary studies—observations on the actual food habits—of the preschool child as the best current procedure to establish food requirements in the early years after infancy. Dietary studies of individual children furnish the most desirable data. As one writer remarks: "It should be

3. Davidson, P. B.: *The Development of Deficiency Disease During Therapeutic Diets*, J. A. M. A. 90: 1014 (March 31) 1928.

1. Four volumes dealing with the growth and development of the child have been edited under the direction of Dr. Kenneth D. Blackfan and published by the Century Company, New York.

remembered that each individual child has his own caloric needs which may vary from that of others of the same age and size. This optimum is such that the child grows properly, feels well, is mentally and physically alert, and adjusts himself to his environment. Standards of food intake are of value in improving the welfare of children, but should not be used to the exclusion of the consideration of the problem of the individual child."

It is a truism that the amount of protein in children's diets should be sufficient to provide for growth, as well as for replacement of protein lost through the "wear and tear" constantly going on in the organism. What does the protein requirement represent in actual figures? A summary prepared by McKay and Evans² indicates, for healthy children of preschool age, a customary protein intake equivalent to from 2.6 to 3.3 Gm. per kilogram of body weight. This is, as might be expected, far greater than that of the adult man of 70 Kg., who consumes approximately 100 Gm. of protein a day. The preschool child adds to its protoplasmic masses quite rapidly during growth. The observations by McKay and Evans of "normal, healthy children" of nursery school age, in the Middle West, showed approximately 2.7 Gm. per kilogram of body weight, or 1.1 Gm. of protein per inch of body height. The protein intake of each child also varied considerably from day to day. Milk supplied slightly more than 50 per cent of the total protein, cereals 19 per cent, meat and eggs 19 per cent, fruit and vegetables 9 per cent, and fatty foods the remainder. Approximately 13 per cent of the total calories were derived from protein. Such a dietary is in general evidently consistent with good physical development in preschool children.

Current Comment

THE EARLY DIAGNOSIS OF MALIGNANT DISEASE

Malignant disease usually starts in one spot, possibly in an individual cell, and in the early stages is painless. A painless tumor or swelling therefore should never be disregarded. Malignant disease may advance for a time without causing symptoms or any disturbances in normal functions. In view of the inherent nature of cancer to spread or to invade distant areas, the earlier the patient submits to proper treatment the greater are his chances of recovery. Sir Holburt Waring,¹ president of the Royal College of Surgeons, has recently listed again the methods of examination that are available to the physician for the diagnosis of early malignant disease. A tumor observed by the patient or friends should be examined at once by a competent clinician. The examination should comprise visual observation of the tumor and palpation to determine its consistency

and connection with adjacent tissues. The clinician should determine whether the tumor is solid or fluid, the margins in relation to surrounding tissues should be determined, and the presence or absence of pain on manipulation should be noted. As most malignant tumors are opaque, the swelling should be transilluminated. After the local examination, the lymphatic glands that drain the affected area should be palpated. A solid enlargement of lymphatic glands may help to confirm the diagnosis of cancer. When a tumor is noted near one of the normal openings of the body it should be examined with the finger, or with the eyes through some special instrument such as the postnasal mirror or the rhinoscope to examine the nasal cavity, the esophagoscope to examine the esophagus, and the bronchoscope to examine the bronchi. The rectum and lower part of the colon can be examined through the tube of a sigmoidoscope, and the interior of the bladder with a cystoscope. When solid or liquid material can be obtained from a suspected lesion, it should be examined by the microscope. Sometimes particles of a cancer may be seen in the blood-stained discharge from the nipple. When a swelling is accessible it is not difficult to remove a portion for histologic examination. The specimen should be taken at the junction of the normal tissue and the suspected tumor and should be cut at right angles to the surface. The risk in doing biopsy of spreading the tumor when it is malignant, the writer says, probably can be avoided by the use of a diathermy knife in detaching a small portion. A roentgen examination may give valuable aid, especially when there is a suspicion of cancer of the alimentary canal. The roentgenograms should be made and interpreted by an expert radiologist after a conference with the clinician. This method applies also to the investigation of suspected tumors of bone and some other tissues. Definite diagnosis frequently demands the services of a diagnostic "team," including a clinician, a radiologist, a pathologist and a surgeon. Too much reliance, however, is sometimes placed on the histologic appearance of tissue removed at biopsy, and sometimes on the roentgen examination alone. According to Bennett,² roentgen examination will reveal cancer of the stomach in the early stages in nearly every case. The precision of such an examination has increased so rapidly that even many physicians are not aware of the exactitude with which diagnosis can be reached. The chemical examination in the diagnosis of cancer of the alimentary tract is important. Few cases will fail to give a positive test for blood in the stools or fail to reveal dependable evidence in a carefully made analysis of the stomach contents. There are now available quite accurate methods of examination and various tests that may be applied in the early diagnosis of cancer in various regions of the body. Gradually the public is becoming more and more aware of what scientific medicine has to offer in saving life when cancer threatens. When popular education has been developed to the utmost, many thousands more will consult their physicians early enough to permit control by the established methods now available.

PROCEEDINGS OF THE MILWAUKEE SESSION

MINUTES OF THE EIGHTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT MILWAUKEE, JUNE 12-16, 1933

(Concluded from page 53)

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Reginald Fitz, Boston.

Dr. Walter L. Bierring, Des Moines, Iowa, read a paper on "Myocardosis: Its Recognition and Therapy." Discussed by Drs. R. I. Rizer, Minneapolis; Cadis Phipps, Boston, and Walter L. Bierring, Des Moines, Iowa.

Drs. William D. Stroud, Philadelphia, Melville A. Goldsmith, Jenkintown, Pa., D. Stewart Polk, Rosemont, Pa., and Francis Z. Thorp, Philadelphia, presented a paper on "Ten Years' Observation of Children with Rheumatic Heart Disease." Discussed by Drs. T. Duckett Jones, Boston; Albert G. Young, Boston, and William D. Stroud, Philadelphia.

Dr. Walter L. Bierring, Des Moines, Iowa, introduced the lecturer for this year, Dr. Lewis A. Conner, New York, who read a paper on "Review of the Development of Knowledge Concerning the Role of Syphilis in Cardiovascular Disease."

Dr. Irving S. Wright, New York, read a paper on "The Clinical Value of Human Capillary Studies." Discussed by Drs. Soma Weiss, Boston; Nelson W. Barker, Rochester, Minn., and Irving S. Wright, New York.

Dr. Samuel A. Levine, Boston, read a paper on "The Systolic Murmur: Its Clinical Interpretation." Discussed by Drs. James B. Herrick, Chicago; Fred M. Smith, Iowa City, and Samuel A. Levine, Boston.

THURSDAY, JUNE 15—MORNING

Dr. Garnett Cheney, San Francisco, read a paper on "The Treatment of the Anemia Associated with Disorders of the Liver: Its Response to Secondary Anemia, Liver Extract and Iron Therapy." Discussed by Drs. William P. Murphy, Boston; Cyrus C. Sturgis, Ann Arbor, Mich.; Reginald Fitz, Boston; Walter E. Simmonds, Chicago, and Garnett Cheney, San Francisco.

Dr. John P. Anderson, Cleveland, read a paper on "Hereditary Gaucher's Disease." Discussed by Drs. Dean Lewis, Baltimore; Norbert Enzer, Milwaukee, and John P. Anderson, Cleveland.

Drs. C. T. Stone and Meyer Bodansky, Galveston, Texas, presented a paper on "The Treatment of Polycythemia Vera: Report of Two Cases." Discussed by Drs. Charles F. Martin, Montreal; Moses Barron, Minneapolis; Nathan Rosenthal, New York, and C. T. Stone, Galveston, Texas.

Drs. Charles H. Watkins and Herbert Z. Giffin, Rochester, Minn., presented a paper on "Experience with Administration of Yellow Bone Marrow in the Treatment of Various Forms of Granulocytopenia." Discussed by Drs. H. N. Harkins, Chicago; F. W. Madison, Milwaukee, and Charles H. Watkins, Rochester, Minn.

Dr. Ralph A. Kinsella, St. Louis, read a paper on "Types of Chronic Rheumatism." Discussed by Drs. James S. McLester, Birmingham, Ala.; Walter Bauer, Boston, and Archer O'Reilly, St. Louis.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. C. T. Stone, Galveston, Texas; vice chairman, Dr. F. W. Madison, Milwaukee; secretary, Dr. William J. Kerr, San Francisco; delegate, Dr. James S. McLester, Birmingham, Ala.; alternate,

Dr. J. E. Paullin, Jr., Atlanta, Ga.; Executive Committee: Dr. C. T. Stone, Galveston, Texas; Dr. Reginald Fitz, Boston; Dr. G. Gill Richards, Salt Lake City.

On motion of Dr. Bunce, regularly seconded, the following resolution was adopted for transmission to the editor of THE JOURNAL for publication:

This section during the past year has lost by death its two most valued members. In the entire life of the American Medical Association no other two men have exerted such a happy influence on the affairs of this section or have done so much to maintain the high character of its deliberations as did Drs. Frank Billings and William Sidney Thayer.

The intellectual strength of Dr. Billings, his clear vision, his straightforward character, and his likability brought forth the affectionate esteem of all of us. This section will feel his fine influence many years to come.

Dr. Thayer's high ideals, his deep learning, his lovable character and his delightful personality produced a lasting influence on American medicine, and his going leaves a keenly felt vacancy in our consciousness. If we can speak of the pure in heart in medicine, that was Dr. Thayer.

Dr. J. M. Blackford, Seattle, read a paper on "Cholecystitis: A Study Based on a Follow-Up After Five to Fifteen Years of Two Hundred Patients Not Operated On." Discussed by Drs. Frank Smithies, Chicago; James F. Weir, Rochester, Minn., and J. M. Blackford, Seattle.

Drs. John H. Musser and D. O. Wright, New Orleans, presented a paper on "Hypertension, Obesity and Hyperglycemia." Discussed by Drs. Henry J. John, Cleveland; Hugo R. Romy, Chicago; Frederick A. Willins, Rochester, Minn.; Francis D. Murphy, Milwaukee; Emmett F. Horner, Louisville, Ky.; E. R. Nuzum, Santa Barbara, Calif., and John H. Musser, New Orleans.

Dr. Reginald Fitz, Boston, read the chairman's address, entitled "The Importance of Clinical-Pathologic Conferences in the Work of the Practitioner as Teacher."

Dr. H. B. Mulholland, University, Va., read a paper on "Pellagra: Review of Cases with Special Reference to the Gastric Secretions." Discussed by Drs. T. D. Spies, Cleveland; W. H. Sebrell, Jr., Washington, D. C.; J. S. McLester, Birmingham, Ala.; Frank Smithies, Chicago; A. L. Levin, New Orleans, and H. B. Mulholland, University, Va.

Dr. H. A. Reimann, Minneapolis, read a paper on "Primary Staphylococcic Pneumonia." Discussed by Drs. Leo G. Rigler, Minneapolis, and W. D. Sutliff, Boston.

Dr. LeRoy S. Peters, Albuquerque, N. M., read a paper on "Intrapleural and Extrapleural Pneumolysis in the Treatment of Pulmonary Tuberculosis." Discussed by Dr. J. A. Myers, Minneapolis.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Fred W. Rankin, Lexington, Ky.

Dr. Arnold S. Jackson, Madison, Wis., read a paper on "The Prevention of Complications in Thyroid Surgery." Discussed by Dr. Robert S. Dinsmore, Cleveland.

Dr. Alfred A. Strauss, Chicago, read a paper on "Cholecoduodenostomy and Gastro-Enterostomy for Chronic Biliary Stasis." Discussed by Drs. J. Tate Mason, Seattle; Waltman Walters, Rochester, Minn., and Alfred A. Strauss, Chicago.

Dr. Donald B. Wells, Hartford, Conn., read a paper on "The Aseptic Tannic Acid Treatment of Diffuse Superficial Burns."

Dr. H. L. Updegraff, Hollywood, Calif., read a paper on "Reconstructive Surgery and Old Facial Burns."

These two papers were discussed by Drs. S. J. Seeger, Milwaukee; Ferris Smith, Grand Rapids, Mich.; D. C. Enloe, Sherman, Texas, and Donald B. Wells, Hartford, Conn.

Dr. Stuart W. Harrington, Rochester, Minn., read a paper on "Symptomatology, Surgical Treatment and Results in Sixty Cases of Diaphragmatic Hernia." Discussed by Drs. C. A. Hedblom, Chicago; Lloyd Noland, Birmingham, Ala., and Stuart W. Harrington, Rochester, Minn.

Dr. Harold L. Foss, Danville, Pa., read a paper on "The Relative Merits of Spinal and Inhalation Anesthesia." Discussed by Drs. John S. Lundy, Rochester, Minn., and George W. Crile, Cleveland.

THURSDAY, JUNE 15—AFTERNOON

Dr. Henry W. Cave, New York, read a paper on "The Incidence and Prevention of Incisional Hernias." Discussed by Drs. Amos R. Koontz, Baltimore; Robert L. Payne, Norfolk, Va., and George A. Hendon, Louisville, Ky.

Dr. W. James Gardner, Cleveland, read a paper on "Removal of the Right Cerebral Hemisphere: Presentation of a Case." Discussed by Dr. Winchell McK. Craig, Rochester, Minn.

Dr. Fred W. Rankin, Lexington, Ky., read the chairman's address, entitled "The Curability of Cancer of the Colon, Rectosigmoid and Rectum."

Dr. Frank H. Lahey, Boston, read a paper on "Esophageal Diverticulum." Discussed by Drs. C. T. Sturgeon, Los Angeles; Roy D. McClure, Detroit, and Frank H. Lahey, Boston.

Dr. Norman S. Shenstone, Toronto, read a paper on "Surgical Indications in Bronchiectasis." Discussed by Drs. C. A. Hedblom, Chicago, and Norman S. Shenstone, Toronto.

Dr. Anatole Kolodny, Sioux City, Iowa, read a paper on "Results of Surgery in Spina Bifida." Discussed by Drs. W. James Gardner, Cleveland, and Harry E. Mock, Chicago.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. Harold Brunn, San Francisco; vice chairman, Dr. Roy D. McClure, Detroit; secretary, Howard M. Clute, Boston; delegate, J. Tate Mason, Seattle; alternate, Frank H. Lahey, Boston.

Dr. Gabriel Tucker, Philadelphia, read a paper on "Bronchoscopic Aid in the Diagnosis and Treatment of Postoperative Pulmonary Complications." Discussed by Dr. Ethian Flagg Butler, Elmira, N. Y.

Dr. William E. Ladd, Boston, read a paper on "Congenital Obstruction of the Small Intestine." Discussed by Drs. Albert H. Montgomery, Chicago; Warren H. Cole, St. Louis, and Frank K. Boland, Atlanta, Ga.

Dr. Thomas G. Orr, Kansas City, Mo., read a paper on "The Indications for Enterostomy." Discussed by Drs. W. D. Gatch, Indianapolis; J. Shelton Horsley, Richmond, Va., and George A. Hendon, Louisville, Ky.

Drs. O. H. Wangenstein and John R. Paine, Minneapolis, read a paper on "The Treatment of Acute Intestinal Obstruction by Suction with the Duodenal Tube." Discussed by Drs. Erwin R. Schmidt, Madison, Wis.; Willard Bartlett, Jr., St. Louis, and O. H. Wangenstein, Minneapolis.

Dr. Loyal Davis, Chicago, read a paper on "The Surgical Relief of Intractable Pain." Discussed by Drs. Max M. Peet, Ann Arbor, Mich., and John L. Garvey, Milwaukee.

Dr. Ernest H. Gaither, Baltimore, read a paper on "Eventual Results of Gastric Surgery." Discussed by Drs. J. Shelton Horsley, Richmond, Va., Alfred A. Strauss, Chicago, and Ernest H. Gaither, Baltimore.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Barton Cooke Hirst, Philadelphia.

On motion of Dr. E. D. Plass, Iowa City, seconded by Dr. W. F. Seeley, Detroit, it was voted to nominate Dr. Reuben Peterson, Ann Arbor, Mich., former professor of obstetrics and gynecology at the University of Michigan Medical School, for Honorary Fellowship.

Dr. Lee Bivings, Atlanta, Ga., read a paper on "Preconceptional and Prenatal Influences Affecting the New-Born." Discussed by Drs. Fred L. Adair, Chicago; Raymond L. Schulz, Los Angeles, and Lee Bivings, Atlanta, Ga.

Drs. W. T. McConnell and Roland L. McCormack, Louisville, Ky., read a paper on "Carbon Dioxide and Oxygen in Obstetrics." Discussed by Drs. Walter M. Boothby, Rochester, Minn.; E. D. Plass, Iowa City; Henry F. Beckman, Indianapolis, and W. T. McConnell, Louisville, Ky.

Dr. J. P. Greenhill, Chicago, read a paper on "Infiltration Versus Spinal Anesthesia in Obstetrics." Discussed by Drs. Joseph B. De Lee, Chicago; F. H. Falls, Chicago, and J. P. Greenhill, Chicago.

Dr. Leroy A. Calkins, Kansas City, Mo., read a paper on "Management of the Third Stage of Labor." Discussed by Drs. Jennings C. Litzenberg, Minneapolis; F. J. Schatz, St. Cloud, Minn.; Henry P. Newman, San Diego, Calif.; E. L. Cornell, Chicago, and Leroy A. Calkins, Kansas City, Mo.

Dr. Stuart B. Blakely, Binghamton, N. Y., read a paper on "Abdominal Pain in Pregnancy." Discussed by Drs. Rae T. La Vake, Minneapolis, and Stuart B. Blakely, Binghamton, N. Y.

Dr. Edward L. King, New Orleans, read a paper entitled "Does Quinine as Used in Induction of Labor Have a Deleterious Effect on the Fetus?" Discussed by Drs. F. H. Falls, Chicago, and Edward L. King, New Orleans.

THURSDAY, JUNE 15—MORNING

Dr. E. D. Plass, Iowa City, read a paper on "Gestational Polyneuritis." Discussed by Drs. Ralph H. Luikart, Omaha; J. H. Surc, Milwaukee; Rae T. La Vake, Minneapolis; F. H. Falls, Chicago; F. J. Schatz, St. Cloud, Minn., and E. D. Plass, Iowa City.

Dr. C. H. Peckham, Baltimore, read a paper on "Fetal Mortality in the Toxemias of Pregnancy." Discussed by Drs. John W. Harris, Madison, Wis.; Fred L. Adair, Chicago; Joseph B. De Lee, Chicago; A. C. Posner, New York, and C. H. Peckham, Baltimore.

Dr. Barton Cooke Hirst, Philadelphia, read the chairman's address, entitled "The Four Major Problems of Gynecology."

Dr. John P. Gardiner, Toledo, Ohio, read a paper on "Fetal Risks in the First Stage of Labor from Umbilical Cord Complications." Discussed by Drs. William J. Dieckman, Chicago; E. L. King, New Orleans; W. Parks Phillips, La Grange, Ga., and John P. Gardiner, Toledo, Ohio.

Dr. August A. Werner, St. Louis, read a paper on "Minimum Theelin Dosage Necessary to Stimulate Endometrial Changes in Castrated Women." Discussed by Drs. Emil Novak, Baltimore; J. P. Pratt, Detroit; E. B. Woods, Iowa City, and August A. Werner, St. Louis.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. Joseph B. De Lee, Chicago; vice chairman, Dr. Paul Titus, Pittsburgh; secretary, Dr. James R. McCord, Atlanta, Ga.; delegate, Arthur H. Curtis, Chicago; alternate, Carl Henry Davis, Milwaukee.

The following recommendations of the Executive Committee were adopted:

1. Formal approval of the resolution passed Monday requesting of the House of Delegates that Dr. Reuben R. Peterson, Ann Arbor, Mich., be made an Honorary Fellow of the Association.

2. That the section delegate at the next annual meeting submit to the House of Delegates the name of Dr. Howard A. Kelly, Baltimore, for honorary membership in the Association.

The Secretary read the following report of the Committee on Maternal Welfare, which was adopted:

During the past few years all of the members of your committee have occupied important positions on the Subcommittee on Maternal Care of the White House Conference on Child Health and Protection. One volume resulting from the work of this subcommittee dealing with obstetric education has been published; another volume on obstetric morbidity and mortality is in press; other publications will follow which will conclude the work in this field. Two members of your committee have served on the advisory committee concerned with the maternal mortality study of the federal Children's Bureau. This study has been carried on with the cooperation of the state medical societies of thirteen or fifteen selected states. It is now completed and in press. Your committee has served as a part of the Joint Committee on Maternal Welfare, whose time has largely been absorbed in the above-mentioned activities. A

meeting of this joint committee has been held at this session and activities have been planned for the ensuing year. We feel that the medical profession in certain communities is actively assuming leadership in approaching the problems of maternal welfare. This is most desirable and such activities should be continued and extended. Your committee and its members will continue to do what it can to stimulate and assist the medical profession and its members to activity in this field of human welfare. We respectfully submit this report and suggest that the committee be continued.

RUDOLPH W. HOLMES.

ROBERT MUSSEY.

FRED L. ADAIR, Chairman.

Dr. Emery Moore Fitch, Claremont, N. H., read a paper on "Crises of the Female Pelvis: Treated by the General Surgeon." Discussed by Drs. John F. Gile, Hanover, N. H.; Howard M. Clute, Boston; Joseph L. Baer, Chicago, and Emery Moore Fitch, Claremont, N. H.

Dr. Richard W. TeLinde, Baltimore, read a paper on "Cancer-Like Lesions of the Uterine Cervix." Discussed by Drs. George H. Gardner, Chicago, and Richard W. TeLinde, Baltimore.

Dr. Norman F. Miller, Ann Arbor, Mich., read a paper on "Posture and Dysmenorrhea: Report on a Four Year Study on 302 Young Women." Discussed by Drs. Carl Henry Davis, Milwaukee; Joseph L. Baer, Chicago; Marie Levinson, Bronx, N. Y.; L. L. Cullimore, Provo, Utah, and Norman F. Miller, Ann Arbor, Mich.

Dr. Virgil S. Counsellor, Rochester, Minn., read a paper on "Management of Chronic Pelvic Infection." Discussed by Drs. Francis W. Sovak, New York; Carl Henry Davis, Milwaukee, and Virgil S. Counsellor, Rochester, Minn.

Dr. Frederick S. Wetherell, Syracuse, N. Y., read a paper on "Relief of Pelvic Pain by Sympathetic Neurectomy." Discussed by Drs. J. P. Greenhill, Chicago; C. H. Frazier, Philadelphia, and Frederick S. Wetherell, Syracuse, N. Y.

Dr. Harold E. Simon, Birmingham, Ala., read a paper on "Colpectomy." Discussed by Dr. James C. Masson, Rochester, Minn.

SECTION ON OPHTHALMOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Frederick H. Verhoeff, Boston.

Dr. Frederick H. Verhoeff, Boston, read the chairman's address, entitled "Ophthalmology as a Career."

Dr. T. B. Holloway, Philadelphia, presented the following resolution, for submission to the House of Delegates:

WHEREAS, Prenatal syphilis is responsible for interstitial keratitis and for many uveal and neural changes resulting in defective sight and blindness as well as deafness and other defects; and

WHEREAS, It has been found that above 3 per cent of the women attending prenatal clinics—in certain studies as high as 30 per cent—have shown a positive reaction to the Wassermann test, and it has been estimated on the basis of group studies that from 3 to 5 per cent of children taken in the mass have prenatal syphilis and that about half of these children without adequate treatment develop interstitial keratitis leading to defective vision if not blindness; and

WHEREAS, It has been authoritatively stated that prenatal syphilis can, without doubt, be prevented in the majority of cases, but only if there is complete cooperation between the patient and the various medical, social and educational agencies which enter into the diagnosis, the treatment and the care of the infected pregnant woman; and if treated adequately in the child before organic changes have occurred, is curable without loss of sight; and

WHEREAS, This deplorable condition can be controlled only by combined efforts of the medical, the social and public health authorities; therefore be it

Resolved, That this section requests the House of Delegates of the American Medical Association to appoint a committee to take this subject under advisement and to arrange methods by which cooperation may be secured through the combined efforts of the American Medical Association, the National Society for the Prevention of Blindness, the American Social Hygiene Association, the obstetric and ophthalmologic societies, the American Dermatological Association, public health organizations and such other organizations as can help, in order that blood examinations may be made of all pregnant women so that methods may be arranged for the treatment of all those infected with syphilis, thereby preventing the blindness and other tragedies which would otherwise inevitably follow.

On motion of Dr. Holloway, seconded by Dr. F. Park Lewis, Buffalo, the resolution was adopted.

Dr. N. K. Lazar, Chicago, read a paper on "The Effect of Tryparsamide on the Eye: An Experimental and Clinical Study and Report of a Case." Discussed by Drs. John H. Stokes, Philadelphia; Emory Hill, Richmond, Va.; F. A. Davis, Madison, Wis.; George N. Hosford, San Francisco; George F. Suker, Chicago; Leo L. Mayer, Chicago, and N. K. Lazar, Chicago.

Dr. Algernon B. Reese, New York, read a paper on "The Ciliary Processes and Their Relation to Intra-Ocular Surgery." Discussed by Dr. William C. Finnoff, Denver.

Dr. Edward Jackson, Denver, read a paper on "Practical Lenses: A Trial Set." Discussed by Drs. William E. Shahan, St. Louis; S. Judd Beach, Portland, Maine; William H. Crisp, Denver, and Edward Jackson, Denver.

Dr. Arthur M. Yudkin, New Haven, Conn., read a paper on "The Clinical Implications of Ocular Disturbances Produced in Experimental Animals by Dietary Changes." Discussed by Drs. C. S. O'Brien, Iowa City; K. W. Cosgrove, Little Rock, Ark.; Paul L. Day, Little Rock, Ark.; Laura A. Lane, Minneapolis, and Arthur M. Yudkin, New Haven, Conn.

Dr. William H. Crisp, Denver, read a paper on "Standards and Licensure in Ophthalmology." Discussed by Drs. T. B. Holloway, Philadelphia, and William H. Crisp, Denver.

Dr. Peter C. Kronfeld, Chicago, read a paper on "The Function of the Reattached Retina." Discussed by Drs. William L. Benedict, Rochester, Minn.; Clifford B. Walker, Los Angeles; V. A. Chapman, Milwaukee, and Peter C. Kronfeld, Chicago.

THURSDAY, JUNE 15—AFTERNOON

Dr. Thomas D. Allen, Chicago, gave a demonstration of the pathology of bullous keratitis.

Dr. Leo L. Mayer, Chicago, showed a hand slate and a method of recording visual fields.

Dr. David W. Wells, Boston, presented a modified instrument for testing depth perception after Bishop-Harman.

Dr. Clifford B. Walker, Los Angeles, described his instruments and the technic of scleral puncture for treating detachment of the retina by diathermy.

Dr. V. A. Chapman, Milwaukee, demonstrated safety spectacles for the color blind.

Dr. Oscar B. Nugent, Chicago, demonstrated superior rectus muscle forceps and an oral vacuum control valve and modified Green's suction cup.

Dr. Daniel B. Kirby, New York, presented matched cataract instruments with better steel in knife blades.

Dr. Harry S. Gradle, Chicago, presented experimental glasses for reducing vision.

Dr. Harry S. Gradle, Chicago, read a paper on "Critical Analysis and Comparison of Two Hundred Consecutive Cases of Cataract Intracapsular and Extracapsular Extraction." Discussed by Drs. Arnold Knapp, New York; Walter R. Parker, Detroit; Warren D. Horner, San Francisco; Jasper M. Molsberry, Iowa City; Otis R. Wolfe, Marshalltown, Iowa; Walter B. Lancaster, Boston; V. A. Chapman, Milwaukee, and Harry S. Gradle, Chicago.

Dr. Oscar B. Nugent, Chicago, read a paper on "Cataract Complications in Relation to Intra-Ocular Tension and Blood Pressure." Discussed by Drs. John Green, St. Louis, and Oscar B. Nugent, Chicago.

Dr. George P. Guibor, Chicago, read a paper on "A Study of the Possibilities of Orthoptic Training: Preliminary Report." Discussed by Drs. Luther C. Peter, Philadelphia; David W. Wells, Boston; Sanford R. Gifford, Chicago; Conrad Berens, New York; Thomas D. Allen, Chicago, and George P. Guibor, Chicago.

Dr. Henry P. Wagener, Rochester, Minn., read a paper on "The Arterioles of the Retina in Toxemia of Pregnancy." Discussed by Drs. Robert J. Masters, Indianapolis; Arthur J. Bedell, Albany, N. Y., and Henry P. Wagener, Rochester, Minn.

Drs. Warren D. Horner and Sol Maisler, San Francisco, presented a paper on "Ectopia Lentis, with Case Report of Total Dislocation Directly Downward." Discussed by Dr. William Zentmayer, Philadelphia.

Dr. Derrick T. Vail, Jr., Cincinnati, read a paper on "Mixed (Teratoid) Tumors of the Lacrimal Caruncle." Discussed by Dr. Thomas D. Allen, Chicago.

Dr. A. Beulah Cushman, Chicago, read a paper on "Visual Field Studies in Functional Headache of Pituitary Origin." Discussed by Dr. Clifford B. Walker, Los Angeles.

FRIDAY, JUNE 16—AFTERNOON

The members of the section stood in silence for a minute in memory of Dr. Albert E. Bulson.

The report of the Committee on Compensation Tables was read by Dr. Harry Gradle, and on motion of Dr. George F. Suker, Chicago, seconded by Dr. Arthur J. Bedell, Albany, N. Y., the report was accepted and the committee continued.

Edward Jackson, chairman, presented the report of the American Committee on Optics and Visual Physiology. On motion of Dr. Suker, seconded by Dr. Bedell, the report was adopted.

The report of the Committee on the Knapp Testimonial Fund was presented by Dr. Parker Heath. On motion of Dr. Bedell, seconded by Dr. Jackson, the report was adopted.

Dr. Clifford B. Walker, chairman, presented the report of the Committee on Awarding the Knapp Medal. On motion of Dr. Suker, seconded by Dr. Emory Hill, Richmond, Va., the report was accepted.

The report of the American Board for Ophthalmic Examinations was presented by Dr. William H. Crisp. On motion of Dr. Suker, seconded by Dr. Bedell, the report was adopted.

The report of the Committee on National Museum of Ophthalmic Pathology was presented for Dr. J. S. Friedenwald by the secretary. On motion of Dr. Bedell, duly seconded, the report was accepted and the committee continued.

As no member of the Committee from the Section to Cooperate with the National Committee for the Prevention of Blindness was present, the report as given with resolution Wednesday afternoon was accepted, and on motion of Dr. Bedell, duly seconded, was carried.

Dr. Parker Heath, chairman, presented the report of the Committee for Scientific Exhibit from the section. On motion of Dr. Hill, seconded by Dr. Bedell, the report was accepted and the chairman reappointed.

The report of the Committee to Confer with the National Conference on Nomenclature of Disease was presented by Dr. Walter B. Lancaster. On motion of Dr. Bedell, seconded by Dr. Suker, the report was received, the committee continued, and a vote of thanks tendered the members of the committee for their arduous work.

Dr. Edward Stieren, the delegate, not being present, on motion of Dr. Suker, seconded by Dr. Hill, the report Dr. Stieren made to the House of Delegates on June 15 was accepted as his report to the section.

The following officers were elected: chairman, Dr. William C. Finnoff, Denver; vice chairman, Dr. Frank E. Burch, St. Paul; secretary, Dr. Parker Heath, Detroit; delegate, Dr. George F. Suker, Chicago; alternate, Dr. Emory Hill, Richmond, Va.; member of American Board for Ophthalmic Examinations, to fill the three-year term expired of Dr. William H. Crisp, Dr. E. C. Ellett, Memphis, Tenn.; to fill two vacancies on the American Committee on Optics and Visual Physiology, Drs. Walter B. Lancaster, Boston, and William H. Luedde, St. Louis.

The Executive Committee, with the executive member of the permanent committee of the Knapp Testimonial Fund, recommended for treasurer of this fund to replace Dr. Albert E. Bulson, deceased, Dr. Parker Heath, Detroit.

The Executive Committee recommended the formation of a Committee on Ophthalmic History, to collect portraits, letters and other documents concerning the early ophthalmology of this country, the material to be placed in the permanent custody of the Army Medical Library in Washington, this committee to consist of Drs. Burton Chance, Philadelphia; Arnold Knapp, New York, and Harry Friedenwald, Baltimore.

The Executive Committee recommended the appointment of a committee to consider standards for ophthalmic appliances and drugs, and to make recommendations, this committee to consist of Drs. Francis H. Adler, Philadelphia; Clifford B. Walker, Los Angeles, and Sanford R. Gifford, Chicago, chairman.

The Executive Committee stated that it had the matter of the preessional volume under consideration and recommended that its reinstatement be made at the discretion of the committee.

The Executive Committee recommended that the number of papers at the next session be limited to fifteen, including the chairman's address, as this gives a more equitable division between presentation of papers and discussion.

The Executive Committee recommended that the demonstration session follow the regular reading of papers at one of the sessions.

The following members of the Committee on Awarding the Knapp Medal were nominated and elected from the floor: Drs. Hans Barkan, San Francisco; Arthur J. Bedell, Albany, N. Y., chairman, and Harry Friedenwald, Baltimore.

On motion of Dr. Bedell, seconded by Dr. Hill, the report of the Executive Committee was adopted and the officers therein named were elected.

Dr. Frederick H. Verhoeff, chairman, stated that the award of the Ophthalmic Research Medal of the American Medical Association is made through the Executive Committee of this section and announced that this year no award is made.

The Executive Committee recommended the adoption of the change in name of the American Board for Ophthalmic Examinations to the American Board of Ophthalmology.

Drs. William Campbell Posey, Radnor, Pa., and Lewis H. Carris, New York, presented a paper on "The National Society for the Prevention of Blindness—A Lay Movement for the Conservation of Vision." Discussed by Drs. William H. Wilder, Chicago; Conrad Berens, New York; S. B. Muncaster, Washington, D. C., and Lewis H. Carris, New York.

Dr. A. D. Ruedemann, Cleveland, read a paper on "Conjunctival Vessels." Discussed by Drs. Arthur J. Bedell, Albany, N. Y., and A. D. Ruedemann, Cleveland.

Drs. George N. Hosford and Avery M. Hicks, San Francisco, presented a paper on "The O'Connor Cinch Shortening Operation for Heterotopia and Heterophoria." Discussed by Drs. William F. Hardy, St. Louis; W. D. Horner, San Francisco, and George N. Hosford, San Francisco.

Dr. Charles N. Spratt, Minneapolis, read a paper on "Pocket-Flap Sclerecto-Iridodialysis in Glaucoma." Discussed by Drs. Walter B. Lancaster, Boston; Virgil J. Schwartz, Minneapolis, and Charles N. Spratt, Minneapolis.

Dr. James W. Smith, New York, read a paper on "Spontaneous Dislocation of the Lacrimal Glands." Discussed by Drs. F. Herbert Haessler, Milwaukee; Edward Jackson, Denver; V. A. Chapman, Milwaukee, and James W. Smith, New York.

SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Harris P. Mosher, Boston.

Dr. Harris P. Mosher, Boston, read the chairman's address, entitled "The Involvement of the Esophagus in Acute and Chronic Infection of Neighboring Organs."

On motion of Dr. John J. Shea, Memphis, Tenn., seconded by Dr. Austin A. Hayden, Chicago, it was voted to nominate the following for Associate Fellowship: A. J. Asgis, 310 West Seventy-Second Street, New York; Charles Cronauer, Jr., D.D.S., 100 East Palisade Avenue, Englewood, N. J.; J. Oliver Ericsson, D.D.S., Main and DeKalb streets, Norristown, Pa.; Nathan M. Gassen, D.D.S., 215 West Eighty-Eighth Street, New York; Louis V. Hayes, 576 Fifth Avenue, New York.

Dr. Harry P. Cahill, Boston, read a paper on "Modern Treatment of Brain Abscess." Discussed by Drs. Alfred W. Adson, Rochester, Minn.; R. Eustace Semmes, Memphis, Tenn.; W. James Gardner, Cleveland, and Harry P. Cahill, Boston.

Dr. Robert Sonnenschein, Chicago, read a paper on "Some of the Fundamental Principles of Functional Hearing Tests and Some Recent Developments in Tuning Forks and Sounding Rods." Discussed by Drs. W. H. Theobald, Chicago; Horace Newhart, Minneapolis, and Robert Sonnenschein, Chicago.

Dr. Gordon Berry, Worcester, Mass., read a paper on "The Psychology of Progressive Deafness." Discussed by Drs. Wendell C. Phillips, New York; John F. Curtin, Minneapolis; George E. Shambaugh, Jr., Chicago; William V. Mullin, Cleveland, and Gordon Berry, Worcester, Mass.

Dr. C. E. Cooper, Denver, read a paper on "The Future Market for Medical Service." Discussed by Drs. W. P.

Wherry, Omaha; Burt R. Shurly, Detroit; W. W. Pearson, Des Moines, Iowa; Samuel J. Kopetzky, New York; Charles A. Dukes, Oakland, Calif., and C. E. Cooper, Denver.

Dr. George E. Hourn, St. Louis, read a paper on "The Anatomic Contributions of Dr. Mosher." Discussed by Drs. Gregor W. McGregor, Toronto; William V. Mullin, Cleveland; Thomas E. Carmody, Denver; Homer Dupuy, New Orleans, and Joseph E. Beck, Chicago. Dr. Mosher expressed his thanks and appreciation to the members of the section.

THURSDAY, JUNE 16—MORNING

Dr. Edward F. Ziegelman, San Francisco, read a paper on "The Surgical Importance of the Laryngeal Nerves in Relation to the Thyroid Arteries, Thyroid Gland and Larynx." Discussed by Drs. William A. Kennedy, St. Paul; Robert S. Dinsmore, Cleveland; David D. Berlin, Boston; Charles H. Frazier, Philadelphia, and Edward F. Ziegelman, San Francisco.

Dr. A. C. Furstenberg, Ann Arbor, Mich., read a paper on "Mediastinitis: A Clinical Study with Practical Anatomic Considerations of the Neck and Mediastinum." Discussed by Drs. George W. Crile, Cleveland; Stuart W. Harrington, Rochester, Minn.; Thomas L. Tolan, Milwaukee, and A. C. Furstenberg, Ann Arbor, Mich.

Drs. Chevalier Jackson and Chevalier L. Jackson, Philadelphia, presented a paper on "Pulmonary Complications of Esophageal Disease." Discussed by Drs. Gabriel Tucker, Philadelphia; John B. Potts, Omaha; Samuel Iglaue, Cincinnati; Herman J. Moersch, Rochester, Minn.; M. F. Arbuckle, St. Louis, and Chevalier Jackson, Philadelphia.

Dr. Henry Boylan Orton, Newark, N. J., read a paper on "A Peculiar Form of Hyperplasia of the Mucous Membrane of the Upper Respiratory Tract." Discussed by Drs. H. M. Goodyear, Cincinnati; Ira Frank, Chicago; John J. Shea, Memphis, Tenn., and Henry Boylan Orton, Newark, N. J.

Dr. Gordon F. Harkness, Davenport, Iowa, read a paper on "The Involuntary Nervous System in Relation to Otolaryngology." Discussed by Drs. Dean M. Lierle, Iowa City; John W. Carmack, Indianapolis; Carl L. Larsen, St. Paul; Howard C. Ballenger, Chicago, and Gordon F. Harkness, Davenport, Iowa.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. W. P. Wherry, Omaha; vice chairman, Dr. Robert F. Ridpath, Philadelphia; secretary, Dr. John J. Shea, Memphis, Tenn.; Executive Committee, Drs. Gabriel Tucker, Philadelphia, Harris P. Mosher, Boston, and W. P. Wherry, Omaha; delegate, Dr. Burt R. Shurly, Detroit; alternate, Dr. Gordon F. Harkness, Davenport, Iowa.

The report of the Committee on Lye Legislation was accepted and the committee continued.

The reports of the Committee on Hygiene of Swimming and the American Board of Otolaryngology were received and placed on file.

The report of the Necrology Committee was accepted and the members of the section stood in silence for a moment in memory of the departed.

Dr. Charles Lukens, Toledo, Ohio, presented a device for binocular single vision to wearers of bifocals using head mirrors.

Drs. Gabriel Tucker and Eugene P. Pendergrass, Philadelphia, reported a case of congenital atresia of the esophagus and presented a method of combined roentgen and esophagoscopic technic.

Dr. Arthur W. Proetz, St. Louis, presented an apparatus for observing ciliary motion.

Dr. Gordon D. Hoople, Syracuse, N. Y., read a paper on "The Otorhinologic Aspects of Scarlet Fever." Discussed by Drs. Irving I. Muskat and Horace R. Lyons, Chicago; O. Jason Dixon, Kansas City, Mo.; Edward D. King, Cincinnati, and Gordon D. Hoople, Syracuse, N. Y.

Dr. Harold I. Lillie, Rochester, Minn., read a paper on "Infection of the Blood Stream Associated with Suppuration in the Temporal Bone." Discussed by Drs. George M. Coates, Philadelphia; James B. Costen, St. Louis, and Harold I. Lillie, Rochester, Minn.

Dr. Arthur W. Proetz, St. Louis, read a paper on "Principles of Sinus Treatment in the Light of Physiologic Facts." Discussed by Drs. Ralph A. Fenton, Portland, Ore.; Anderson

C. Hilding, Duluth, Minn.; J. A. Pratt, Minneapolis, and Arthur W. Proetz, St. Louis.

Dr. Harris H. Vail, Cincinnati, read a paper on "The Treatment of Hay Fever by Alcohol Injections in the Nose." Discussed by Drs. Frank J. Novak, Chicago; Virgil J. Schwartz, Minneapolis; M. F. Arbuckle, St. Louis, and Harris H. Vail, Cincinnati.

Drs. Karl Musser Houser and Eugene P. Pendergrass, Philadelphia, presented a paper on "The Diagnosis and Treatment of Primary Malignant Conditions of the Maxillary Sinuses." Discussed by Drs. Edward C. Sewall, San Francisco; M. R. Guttman, Chicago, and F. Z. Havens, Rochester, Minn.

SECTION ON PEDIATRICS

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:15 by the chairman, Dr. Frederic W. Schlutz, Chicago.

Dr. Frederic W. Schlutz, Chicago, read the chairman's address, entitled "The First Half-Century of the Section on Pediatrics."

Prof. E. Gorter, Leyden, Holland, read a paper on "Post-vaccinal Encephalitis."

Drs. William H. Park, Camille Kereszturi and Lucy Michelow, New York, presented a paper on "BCG Investigation in New York City: The Safety and Immunizing Value of the Vaccine." Discussed by Drs. Horton R. Casparis, Nashville, Tenn.; Karl E. Kassowitz, Milwaukee; Henry J. Gerstenberger, Cleveland; J. A. Myers, Minneapolis; Emil Bogen, Olive View, Calif., and William H. Park, New York.

Dr. S. W. Clausen, Rochester, N. Y., read a paper on "Limits of the Anti-Infective Value of Provitamin A (Carotene)." Discussed by Drs. Henry J. Gerstenberger, Cleveland, and I. Newton Kugelmass, New York.

Dr. Jean V. Cooke, St. Louis, read a paper on "Acute Leukemia in Children." Discussed by Dr. F. C. Rodda, Minneapolis.

Dr. Charles Glenville Giddings, Jr., Atlanta, Ga., read a paper on "The Normal Sleep Pattern for Children and the Factors That Can Derange Such Pattern." Discussed by Drs. M. Hines Roberts, Atlanta, Ga.; C. Ulysses Moore, Portland, Ore., and Charles Glenville Giddings, Jr., Atlanta, Ga.

THURSDAY, JUNE 15—AFTERNOON

Drs. Henry J. Gerstenberger, Arthur J. Horesli, G. Richard Russell and Edna E. Chapman, Cleveland, read a paper on "Serum Phosphatase in Infants and Children as Influenced by Various Diseases and Conditions." Discussed by Drs. J. R. Gerstley, Chicago, and Henry J. Gerstenberger, Cleveland.

Dr. Abraham Levinson, Chicago, read a paper on "Acute Transitory Cerebral Manifestations in Infants and Children." Discussed by Drs. M. G. Peterman, Milwaukee, and Abraham Levinson, Chicago.

Drs. E. B. Shaw and H. E. Thelander, San Francisco, presented a paper on "Endemic Cerebrospinal Fever in Childhood." Discussed by Drs. C. A. Aldrich, Winnetka, Ill.; A. B. Schwartz, Milwaukee; Josephine B. Neal, New York; Gilbert J. Levy, Memphis, Tenn., and E. B. Shaw, San Francisco.

Drs. Charles F. McKhann and Edward C. Vogt, Boston, presented a paper on "Lead Poisoning in Infants and Children." Discussed by Drs. R. A. Kehoe, Cincinnati; Robert A. Strong, New Orleans, and Katsuji Kato, Chicago.

Drs. E. Kost Shelton and Lyman A. Cavanaugh, Santa Barbara, Calif., and Herbert M. Evans, New York, presented a paper on "Hypophyseal Infantism: Treatment with an Anterior Hypophyseal Extract." Discussed by Drs. J. Victor Greenebaum, Cincinnati, and E. Kost Shelton, Santa Barbara, Calif.

Drs. Paul C. Hodges, Wright Adams and Wayne Gordon, with the assistance of Benjamin W. Anthony, Chicago, presented a paper on "Estimation of Cardiac Area in Children." Discussed by Drs. Julius H. Hess, Chicago, and Paul C. Hodges, Chicago.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. Alfred A. Walker, Birmingham, Ala.; vice chairman, Dr. C. W. Burhans, Cleveland; secretary, Dr. Ralph M. Tyson, Philadelphia; delegate, Dr. Isaac A. Abt, Chicago; alternate, Dr. A. Graeme Mitchell, Cincinnati; Executive Committee, Drs. Alfred A.

Walker, Birmingham, Ala.; Frederic W. Schlutz, Chicago, and Jay I. Durand, Seattle; representative on Scientific Exhibit, Dr. F. Thomas Mitchell, Memphis, Tenn.

The following resolution, presented by the Executive Committee, was adopted:

Resolved, That the Section on Pediatrics extend a vote of thanks to the Milwaukee colleagues and particularly the vice chairman, Dr. M. G. Peterman, for the extraordinarily fine arrangements provided for the meetings, the splendid entertainment given at the section dinner, and the general hospitality extended to all the members of the section.

Dr. Frank C. Neff, Kansas City, Mo., presented the following report on behalf of the Jacobi Fund Committee:

During the fiscal year just ending, the Section Transactions published by the American Medical Association have been sent to all subscribers to the Jacobi Fund. Arrangements were made for bringing Professor E. Gorter, Leyden, Holland, as our guest for 1933. The Jacobi Fund is paying \$500 toward publishing the festschrift in honor of Czerny, which will appear in the July issue of the *Journal of Pediatrics*.

At the suggestion of Dr. Henry L. K. Shaw of Albany and Dr. Isaac Abt, with the consent of the members of the Jacobi Committee, arrangements have been begun toward erecting a bronze tablet at the entrance to Jacobi's summer home on Lake George which his daughter, Mrs. McEnery, now occupies. As you may recall, Carl Schurz and Abraham Jacobi came together from Germany and were always close friends. They bought property together at Bolton Landing, Lake George. An inscription in stone has been raised to the memory of Carl Schurz, and it is our plan to place one by its side in memory of Jacobi. This will be visible from the highway to all tourists passing Lake George. At a suitable time following its completion, the memorial will be dedicated in the presence of all members of this section who care to be present.

During the year the Jacobi Fund received a check for \$400 from the Association of American Teachers of Diseases of Children.

The committee wishes to express its appreciation of the loyalty and generosity of the members and friends of the Section on Pediatrics.

The financial report is appended.

THE ABRAHAM JACOBI MEMORIAL FUND COMMITTEE.

ISAAC A. ABT, Chairman.
WILLIAM WESTON.
C. ANDERSON ALDRICH.
JAY I. DURAND.
FRANK C. NEFF, Secretary.

The following is the Treasurer's report on the Jacobi Fund:

| | |
|---|-------------------|
| Balance on hand, June 1, 1932..... | \$5,479.16 |
| Receipts: | |
| 132 subscriptions for 1932..... | \$ 707.00 |
| 1 subscription for 1931 (late)..... | 5.00 |
| Interest at Traders Gate City National Bank..... | 19.04 |
| A savings account which permits an occasional check to be written. | |
| Interest at Anchor Sav. & Loan Assn..... | 2.17 |
| Income from Trust Fund..... | 241.96 |
| Contribution from Association of American Teachers of Diseases of Children..... | 400.00 |
| | <u>1,375.17</u> |
| | \$6,854.33 |
| Expenses: | |
| Dr. Krasnogorski | 200.00 |
| Printing announcements and receipt cards.... | 29.87 |
| Envelops | 4.83 |
| Postage | 31.00 |
| Telegrams | 5.80 |
| Exchange check Dr. Parsons, Birmingham, England | .25 |
| 1931 Transactions of Section..... | 1.52 |
| 132 copies 1932 Transactions of Pediatric Section A. M. A..... | 198.02 |
| Expenses Dr. Aycock to section meeting..... | 115.22 |
| | <u>586.51</u> |
| Balance on hand, June 1, 1933..... | \$6,267.82 |
| The fund is held as follows: | |
| On deposit at Traders Gate City National Bank | 661.33 |
| On deposit at Anchor Sav. & Loan Assn..... | 75.02 |
| Trust Fund | 5,531.47 |
| | <u>\$6,267.82</u> |

During the year of 1932 the sum of \$500 was transferred from the savings balance at the Traders to the Trust Fund held by the same bank.

Respectfully submitted.

FRANK C. NEFF, Treasurer.

Dr. Isaac A. Abt, Chicago, retired from the Jacobi Fund Committee, and Dr. Frederic W. Schlutz, Chicago, automatically became a member for a four-year term.

On motion regularly made and seconded, the report of the Jacobi Fund Committee was adopted, with the request that the complete report be published in the Section's Transactions.

Dr. Frederic W. Schlutz, Chicago, expressed the thanks of the section to Professor Gorter for delivering his splendid address.

Dr. Borden S. Veeder, St. Louis, presented the following resolution:

Resolved, That the Section on Pediatrics of the American Medical Association join with the American Academy of Pediatrics and the American Pediatric Society in the formation of an American Board of Pediatrics, for the purpose of certifying to the competence of physicians practicing pediatrics as a specialty.

That the recommendation in regard to the formation of this board, as published in the April 1933 issue of the *Journal of Pediatrics* be adopted.

That the Executive Committee of the Section on Pediatrics appoint three members to this board in the manner outlined in this report.

On motion regularly made and seconded, the resolution presented by Dr. Veeder was adopted.

Drs. Arthur F. Abt and M. I. Vinneccour, Chicago, presented a paper on "Electrocardiographic Studies During Pneumonia in Infants and Children." Discussed by Drs. Louis N. Katz, Chicago; M. H. Nathanson, Minneapolis, and Arthur F. Abt, Chicago.

Dr. I. Newton Kugelmass, New York, read a paper on "Birth Shock of the New-Born and Its Treatment." Discussed by Drs. Ralph M. Tyson, Philadelphia, and I. Newton Kugelmass, New York.

Drs. James D. Trask and Francis G. Blake, New Haven, Conn., read a paper on "Heterologous Scarlet Fever." Discussed by Drs. Jean V. Cooke, St. Louis, and John A. Toomey, Cleveland.

Drs. Ralph M. Tyson, Samuel Goldberg and Nathaniel M. Levin, Philadelphia, presented a paper on "A Clinical Study of Pulmonary Conditions Found in Children in the Chevalier Jackson Bronchoscopic Clinic." Discussed by Dr. Chevalier Jackson, Philadelphia.

Dr. E. S. Platou, Minneapolis, read a paper on "Obstructive Laryngeal Dyspnea in Diphtheritic and Acute Infective Laryngitis." Discussed by Drs. W. Ambrose McGee, Richmond, Va.; Kenneth A. Phelps, Minneapolis, and E. S. Platou, Minneapolis.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. E. M. K. Geiling, Baltimore.

Drs. J. Russell Twiss and Carl H. Greene, New York, presented a paper on "Newer Points of View in the Dietary and Medical Management of Diseases of the Gallbladder." Discussed by Drs. Sidney A. Portis, Chicago; C. B. Wright, Minneapolis; W. D. Mayer, Detroit, and Carl H. Greene, New York.

Drs. Melvin W. Binger and Norman M. Keith, Rochester, Minn., presented a paper on "Study of the Different Types of Edema and the Effect of Diuretics." Discussed by Drs. M. Herbert Barker, Chicago; Edward J. Stieglitz, Chicago, and Norman M. Keith, Rochester, Minn.

Dr. K. K. Chen, Indianapolis, read a paper on "Recent Studies on Toad Poisons." Discussed by Drs. William S. Middleton, Madison, Wis., and K. K. Chen, Indianapolis.

Dr. M. H. Nathanson, Minneapolis, read a paper on "Further Studies of the Effect of Drugs on the Induced Standstill of the Human Heart."

Dr. F. W. O'Connor, New York, read a paper on "The Treatment of Filariasis." No discussion.

THURSDAY, JUNE 15—AFTERNOON

Dr. E. M. K. Geiling, Baltimore, read the chairman's address, entitled "The Need for Conservatism in Endocrine Therapy and Research."

Dr. J. B. Collip, Montreal, read a paper on "The Relationship Between Active Principles of the Placenta and Pregnancy Blood and Urine, and Those of the Anterior Lobe of

the Pituitary, as Indicated by Numerous Experiments on Hypophysectomized Animals." Discussed by Drs. J. P. Pratt, Detroit; Harry Beckman, Milwaukee, and J. B. Collip, Montreal.

Dr. Harry B. Friedgood, Baltimore, read a paper on "Experimental Exophthalmos and Hyperthyroidism in Guinea-Pigs: Clinical Course and Pathology." Discussed by Drs. Walter M. Boothby, Rochester, Minn.; Alexander B. Gutman, New York; J. B. Collip, Montreal; L. M. Zimmerman, Chicago, and Harry B. Friedgood, Baltimore.

Drs. J. G. Reinhold, J. H. Clark, G. R. Kingsley, W. A. Wolff and J. W. McConnell presented a paper on "The Effects of Glycocoll in Muscular Dystrophy, with Especial Reference to Changes in Metabolism and in the Composition of Certain Voluntary Muscles."

Dr. Walter M. Boothby, Rochester, Minn., read a paper on "Myasthenia Gravis."

These two papers were discussed by Harriet Edgeworth, Ph.D., Tucson, Ariz.; Drs. Frederick P. Moersch, Rochester, Minn.; Erwin Brand, New York, and Meyer Solomon, Chicago; Maurice B. Visscher, Ph.D., Chicago, and Drs. M. H. Nathanson, Minneapolis; J. H. Clark, Philadelphia, and Walter M. Boothby, Rochester, Minn.

Dr. Frederick M. Allen, Morristown, N. J., read a paper on "Insulin in the Treatment of Tuberculosis." Discussed by Drs. F. F. Callahan, Pokegama, Minn.; F. M. Pottenger, Monrovia, Calif.; E. S. Nichol, Miami, Fla.; Moses Barron, Minneapolis; William S. Collens, Brooklyn, and Frederick M. Allen, Morristown, N. J.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. John H. Musser, New Orleans; vice chairman, Dr. C. H. Greene, New York; secretary, Dr. Russell L. Haden, Cleveland. The delegate, Dr. N. M. Keith, Rochester, Minn., and the alternate, Dr. Cary Eggleston, New York, hold over from last year.

Phoebe J. Crittenden, Washington, D. C., and P. D. Lamson, Nashville, Tenn., were nominated for Associate Fellowship.

The following papers were read as a symposium on "The Treatment of Acute Infectious Diseases":

Dr. Luke W. Hunt, Chicago: "Therapeutic Results with Scarlet Fever Antitoxin."

Dr. Ward J. MacNeal, New York: "Specific Treatment of Septic Infections, Particularly with Aid of Bacteriophages."

Dr. Lee Foshay, Cincinnati: "An Antiserum for the Treatment of Tularemia."

Dr. Louis W. Sauer, Evanston, Ill.: "Immunization with Bacillus Pertussis Vaccine."

Dr. Yale Kneeland, Jr., New York: "Problems Connected with the Etiology and Prophylaxis of Disease of Upper Respiratory Tract."

These five papers were discussed by Drs. William H. Park, New York; H. A. Reimann, Minneapolis; Raymond P. Schowalter, Milwaukee; Paul S. Rhoads, Evanston, Ill.; Walter M. Simpson, Dayton, Ohio; Gilbert J. Levy, Memphis, Tenn.; Luke W. Hunt, Chicago; Ward J. MacNeal, New York; Louis W. Sauer, Evanston, Ill.; Lee Foshay, Cincinnati, and Yale Kneeland, Jr., New York.

SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. Clyde Brooks, New Orleans.

On motion, regularly made and seconded, it was voted to nominate the following for Associate Fellowship: John A. E. Eyster, Madison, Wis.; Stewart A. Koser, University of Chicago, Chicago; Esmond R. Long, Philadelphia; Valy Menkin, Harvard Medical School, Boston.

Dr. Max Cutler, Chicago, read a paper on "Benign Lesions of the Breast, Simulating Cancer: Diagnosis and Treatment." Discussed by Drs. Frank W. Hartman, Detroit; J. J. Moore, Chicago; J. Shelton Horsley, Richmond, Va.; Arthur F. Abt, Chicago, and Max Cutler, Chicago.

Dr. R. S. Ferguson, New York, read a paper on "The Pathologic Physiology of Teratoma Testis." Discussed by Drs. Frank W. Hartman, Detroit, and R. S. Ferguson, New York.

Drs. A. B. McGraw and F. W. Hartman, Detroit, presented a paper on "The Present State of the Biopsy." Discussed by Drs. William Carpenter MacCarty, Rochester, Minn., and Max Cutler, Chicago.

Drs. Emil Novak and J. Herman Long, Baltimore, presented a paper on "Ovarian Tumors Producing Secondary Sex Changes." Discussed by Drs. Richard W. TeLinde, Baltimore, Fred Krock, Fort Smith, Ark., and Emil Novak, Baltimore.

Dr. A. G. Foord, Pasadena, Calif., read a paper on "Leukemic Reticulo-Endotheliosis—Monocytic Leukemia." Discussed by Drs. Roy R. Kracke, Emory University, Ga.; C. H. Bunting, Madison, Wis.; R. S. Boles, Philadelphia; Frederic E. Sondern, New York; Victor Levine, Chicago, and A. G. Foord, Pasadena, Calif.

Dr. Frank L. Rector, Evanston, Ill., read a paper on "Present-Day Cancer Problems."

THURSDAY, JUNE 15—MORNING

Dr. Clyde Brooks, New Orleans, read the chairman's address, entitled "Nonspecific Protein Therapy."

Dr. Narcisse F. Thiberge, New Orleans, read a paper on "Typhoprotein and Histamine in the Treatment of Asthma." Discussed by Drs. Clyde Brooks, New Orleans; Robert Kapsinow, Lafayette, La.; Leon Unger, Chicago; S. A. Swenson, Oakland, Neb., and Narcisse F. Thiberge, New Orleans.

Dr. A. L. Levin, New Orleans, read a paper on "The Value of Nonspecific Protein in the Treatment of Peptic Ulcer." Discussed by Drs. Robert Kapsinow, Lafayette, La.; Walter E. Vest, Huntington, W. Va.; Sidney A. Portis, Chicago; J. V. S. Dauksys, Excelsior Springs, Mo.; A. A. Herold, Shreveport, La.; William C. MacCarty, Rochester, Minn., and A. L. Levin, New Orleans.

Dr. Clarence A. Neymann, Chicago, read a paper on "The Physiology of Electropexia." Discussed by Drs. William Bierman, New York; Walter M. Simpson, Dayton, Ohio, and Clarence A. Neymann, Chicago.

Dr. Leon Unger, Chicago, read a paper on "Studies on Pollen and Pollen Extracts: The Chemical Nature of Pollen Allergens."

Dr. Maxwell Finland, Boston, read a paper on "A Characterization of Pneumonia Due to Type III Pneumococcus and a Biologically Closely Related Strain Type VIII (Cooper)." Discussed by Drs. W. D. Sutliff, Boston, and Maxwell Finland, Boston.

Dr. Henry J. Corper, Denver, read a paper on "Growing Tubercle Bacilli." Discussed by Drs. Henry C. Sweany, Chicago; A. L. Levin, New Orleans, and Henry J. Corper, Denver.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. William Carpenter MacCarty, Rochester, Minn.; vice chairman, Dr. Elias P. Lyon, Minneapolis; secretary, Dr. J. J. Moore, Chicago; delegate, Dr. D. J. Davis, Chicago; alternate, Dr. J. J. Moore, Chicago; Executive Committee, Drs. J. H. Black, Dallas, Texas; Clyde Brooks, New Orleans, and William Carpenter MacCarty, Rochester, Minn.

Dr. Allan Winter Rowe, Boston, read a paper on "The Toxemias of Pregnancy: IV. The Nitrogen Metabolism." Discussed by Drs. Walter Boothby, Rochester, Minn., and Allan Winter Rowe, Boston.

Dr. E. G. Bannick, Rochester, Minn., read a paper on "Lipoid Nephrosis and Its Relation to Glomerular Nephritis." Discussed by Drs. M. H. Barker, Chicago; Dwight L. Wilbur, Rochester, Minn., and E. G. Bannick, Rochester, Minn.

Drs. Elizabeth M. Koch, Millicent L. Hathaway and Fred C. Koch, Chicago, presented a paper on "The Interpretation of Blood Sugar Values as Obtained by Different Methods."

Drs. George M. Curtis and Francis J. Phillips, Columbus, Ohio, presented a paper on "The Significance of the Iodine Content of Human Blood." Discussed by Drs. Willard O. Thompson, Chicago; R. G. Turner, Detroit, and George M. Curtis, Columbus, Ohio.

Dr. V. H. Moon, Philadelphia, read a paper on "The Pathology of Medical Shock or Circulatory Collapse." Discussed by Drs. J. P. Simonds, Chicago; Louis M. Warfield, Milwaukee; Robert Kapsinow, Lafayette, La., and V. H. Moon, Philadelphia.

Dr. William J. Hoffman, New York, read a paper on "Post-mortem Examinations: Method of Obtaining Permission." Discussed by Drs. F. W. Hartman, Detroit; Israel Davidsohn, Chicago, and William J. Hoffman, New York.

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. George B. Hassin, Chicago.

On motion of Dr. Tom B. Throckmorton, Des Moines, Iowa, regularly seconded and carried, the following resolution was adopted:

WHEREAS, The American Psychiatric Association has appointed from its membership a special board, one of whose duties is to prepare and outline a plan for certification of psychiatrists; and

WHEREAS, It is the opinion of the Section on Nervous and Mental Diseases of the American Medical Association that it should be represented on a certifying board of psychiatry; be it therefore

Resolved, That this section cooperate with the American Psychiatric Association and other national organizations concerned in the formation of such a certifying board by the selection of five of its members.

The following board was appointed by the chairman: Drs. Walter Freeman, Washington, D. C.; Lloyd H. Ziegler, Albany, N. Y.; Edwin G. Zabriskie, New York; T. Allen Jackson, Danville, Pa., and George W. Hall, Chicago.

On motion regularly made, seconded and carried, the following resolution was adopted:

WHEREAS, A knowledge of prevailing methods of providing psychiatric service for courts and other agencies having to do with crime and criminals is essential to the establishment of an adequate psychiatric service on an efficient basis,

Resolved, That the American Medical Association recognizes the desirability of a survey of prevailing methods by which psychiatric service is now provided for courts and other agencies dealing with crime and of the results of such methods; and further

Resolved, That the Association urges its constituent and component societies to devote at least one meeting annually, to which members of the local bar associations shall be invited, for the joint discussion of psychiatric service in the administration of criminal justice and the treatment of the offender.

Dr. Theodora Wheeler, Chicago, read a paper on "Various Aspects of Seizure Graphs in Epilepsy." Discussed by Drs. Roland P. Mackay, Chicago; Richard B. Richter, Chicago, and Theodora Wheeler, Chicago.

Dr. Charles H. Frazier, Philadelphia, read a paper on "A Clinical Survey of Seventy-Eight Verified Tumors of the Frontal Lobe." Discussed by Drs. Alfred W. Adson, Rochester, Minn.; Max M. Peet, Ann Arbor, Mich., and Charles H. Frazier, Philadelphia.

Dr. Roland M. Klemme, St. Louis, read a paper on "The Surgical Treatment of Septic Meningitis." Discussed by Drs. Alfred W. Adson, Rochester, Minn.; Charles H. Frazier, Philadelphia; J. A. Danna, New Orleans, and Roland M. Klemme, St. Louis.

Drs. Paul H. Garvey and John S. Lawrence, Rochester, N. Y., presented a paper on "Facial Diplegia in Lymphatic Leukemia."

Dr. I. B. Diamond, Chicago, read a paper on "Leukemic Changes in the Brain."

These two papers were discussed by Drs. George B. Hassin, Chicago; Richard H. Jaffe, Chicago; Tom B. Throckmorton, Des Moines, Iowa, and Paul H. Garvey, Rochester, N. Y.

Dr. Theodore Diller, Pittsburgh, read a paper on "Lying as a Problem That Concerns the Medical Profession." Discussed by Drs. A. I. Rosenberger, Milwaukee; Lloyd H. Ziegler, Albany, N. Y.; George B. Lake, North Chicago, Ill.; John Favill, Chicago, and Theodore Diller, Pittsburgh.

THURSDAY, JUNE 15—AFTERNOON

On motion regularly made, seconded and carried, the following resolution was adopted:

WHEREAS, Heredosophilis or congenital syphilis is responsible, among its other adverse effects, for the juvenile dementia paralytica and severe emotional problems in children arising from the discomfort and social attitude toward syphilis and the problems of adjustment arising from its effect on vision; and

WHEREAS, Heredosophilis through the early and effective treatment of the infected pregnant woman is a preventable disease, and if treated in the child before organic changes have occurred is curable; and

WHEREAS, It has been found that an average of from 8 to 10 per cent of women in prenatal clinics have positive Wassermann reactions, in various clinics the figures ranging from 3 to 30 per cent, and it has been estimated on the basis of group studies that 2 per cent of children taken in the mass and a considerably larger proportion of those under 1 year of age have heredosyphilis and that about half of these children without adequate treatment develop interstitial keratitis leading to defective vision if not blindness, and that others develop even more serious neural disorders; and

WHEREAS, This deplorable condition can be controlled only by the combined efforts of the medical, the social and the public authorities; therefore, be it

Resolved, That this section requests the House of Delegates of the American Medical Association to appoint a committee to take this subject under advisement and to arrange methods by which cooperation may be secured through the combined efforts of the National Society for the Prevention of Blindness, the American Social Hygiene Association, and professional societies of the syphilologists, obstetricians, ophthalmologists, public health organizations, and such other organizations as can help, in order that blood examinations may be made of all pregnant women so that methods may be arranged for the treatment of all those infected with syphilis, thereby preventing the blindness and other tragedies which would otherwise inevitably follow.

Dr. George B. Hassin, Chicago, read the chairman's address, entitled "So-Called Circulation of the Spinal Fluid."

Dr. Lloyd H. Ziegler, Albany, N. Y., read a paper on "Hysterical Fugues: Report of Cases." Discussed by Drs. Frederick P. Moersch, Rochester, Minn.; George W. Hall, Chicago; Edward E. Mayer, Pittsburgh; Theodore Diller, Pittsburgh, and Lloyd H. Ziegler, Albany, N. Y.

Drs. Meyer M. Harris and Erwin Brand, New York, presented a paper on "Metabolic and Therapeutic Studies in the Myopathies with Special Reference to Glycine Administration." Discussed by Drs. Edwin G. Zabriskie, New York; Hans H. Reese, Madison, Wis., and Meyer M. Harris, New York.

Drs. Paul A. O'Leary and Ashton L. Welsh, Rochester, Minn., presented a paper on "Treatment with Malaria of Neurosyphilis: Observations on 984 Cases in the Last Nine Years." Discussed by Drs. Walter Freeman, Washington, D. C., and Paul A. O'Leary, Rochester, Minn.

Dr. Roy R. Grinker, Chicago, read a paper on "The Results of Treatment of the Neurologic Complications of Pernicious Anemia." Discussed by Drs. Walter F. Schaller, San Francisco; George W. Hall, Chicago; Paul H. Garvey, Rochester, N. Y.; William P. Murphy, Boston; Alexander B. Magnus, Chicago, and Roy R. Grinker, Chicago.

Dr. Tom B. Throckmorton, Des Moines, Iowa, delegate, presented his report.

On motion of Dr. George W. Hall, Chicago, severally seconded, a vote of thanks was extended Dr. Throckmorton.

Drs. Richard E. Stout and Louis J. Karnosh, Cleveland, presented a paper on "Acute Disseminated Encephalomyelitis: Its Clinical Manifestations and Sequelae." Discussed by Drs. Howard D. McIntyre, Cincinnati; Theodore T. Stone, Chicago; Gerald F. Kempf, Indianapolis, and Richard E. Stout, Cleveland.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. Henry W. Woltman, Rochester, Minn.; vice chairman, Dr. Thomas J. Heldt, Detroit; secretary, Henry R. Viets, Boston; delegate, Dr. Tom B. Throckmorton, Des Moines, Iowa; alternate, Dr. Edward Delehanty, Denver; Executive Committee, Drs. Franklin Ebaugh, Denver; George B. Hassin, Chicago, and Henry W. Woltman, Rochester, Minn.

Dr. Carl P. Wagner, Hartford, Conn., read a paper on "The Pharmacologic Action of the Barbiturates and Their Value in Neuropsychiatric Conditions." Discussed by Drs. W. J. Bleckwenn, Madison, Wis.; Walter Freeman, Washington, D. C.; Alexander B. Magnus, Chicago, and Carl P. Wagner, Hartford, Conn.

Drs. Titus H. Harris and Abe Hauser, Galveston, Texas, presented a paper on "The Mechanism of the Anxiety States: Its Importance in General Medicine." Discussed by Drs. George S. Johnson, Denver; A. I. Rosenberger, Milwaukee; Samuel Plahner, Milwaukee; Meyer Solomon, Chicago; George B. Lake, North Chicago, Ill.; Alfred P. Solomon, Chicago, and Titus H. Harris, Galveston, Texas.

Dr. William A. Thomas, Chicago, read a paper on "Generalized Edema Occurring Only at Menstrual Period." Discussed by Drs. George W. Hall, Chicago; Edward Allen, Chicago, and William A. Thomas, Chicago.

Dr. Eric Oldberg, Chicago, read a paper on "Surgical Considerations of Carcinomatous Metastases to the Brain." Discussed by Drs. George W. Hall, Chicago; Winchell McK. Craig, Rochester, Minn., and George B. Hassin, Chicago.

Dr. Winchell McK. Craig, Rochester, Minn., read a paper on "Cerebral Cysts." Discussed by Dr. James W. Kernohan, Rochester, Minn.; Hans H. Reese, Madison, Wis., and J. Rudolph Jaeger, Denver.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Francis Eugene Seneor, Chicago.

Dr. Howard Fox, New York, reported briefly on the activities of the Board of Examiners in Dermatology and Syphilology. On motion of Dr. John Lane, seconded by Dr. James H. Mitchell, and carried unanimously, Dr. Howard Morrow, San Francisco, was elected to succeed himself as a member of this board for a term of four years.

The secretary presented the following resolution for consideration:

WHEREAS, Heredosophilis or congenital syphilis is responsible among its other adverse effects for interstitial keratitis and for many uveal and neural changes resulting in defective sight and blindness; and

WHEREAS, Heredosophilis, through the early and effective treatment of the infected pregnant woman and the child, is a controllable disease; and

WHEREAS, It has been found that an average of from 8 to 10 per cent of women in prenatal clinics have positive Wassermann reactions, in various clinics the figures ranging from 3 to 30 per cent, and it has been estimated on the basis of group studies that 2 per cent of children taken in the mass and a considerably larger proportion of those under 1 year of age have heredosophilis, and that about half of these children without adequate treatment develop interstitial keratitis leading to defective vision if not blindness; and

WHEREAS, This deplorable condition can be controlled only by the combined efforts of the medical, the social and the public health authorities; therefore be it

Resolved, That the Section on Dermatology and Syphilology requests the House of Delegates of the American Medical Association to appoint a committee to take this subject under advisement and to arrange methods by which cooperation may be secured through the combined efforts of the National Society for the Prevention of Blindness, the American Social Hygiene Association, and professional societies of syphilologists and dermatologists, urologists, obstetricians, ophthalmologists, public health organizations and such other organizations as can help.

On motion of Dr. F. D. Weidman, Philadelphia, seconded by Dr. Elmore B. Tauber, Cincinnati, the resolution was adopted.

Dr. F. D. Weidman, Philadelphia, reported briefly for the Committee on Scientific Exhibit and expressed his appreciation of the splendid cooperation of the members of his committee and of the section as a whole. Dr. Weidman stated that the funds contributed to cover the expense of the exhibit were just about exhausted and asked whether it was the wish of the section that the scientific exhibit be continued, and that a collection be taken up among the members as had been the custom in the past. He further stated that no funds had been solicited for four years and that the expenses in connection with the exhibit would become less and less, because each year the central exhibit committee of the American Medical Association assumes more and more of the expense of the scientific exhibits.

Dr. Walter J. Highman, New York, moved that the section take action to perpetuate the exhibit and that an appropriate assessment be levied on the members present. The motion was seconded.

Dr. John E. Lane, New Haven, Conn., offered as an amendment that the chairman ask for voluntary contributions from the members present, and that in view of the low state of finances at present the contributions need not be large.

Dr. Highman accepted Dr. Lane's amendment and the motion as amended was put to a vote and unanimously carried.

Dr. John E. Lane, New Haven, Conn., moved a vote of thanks to Dr. Weidman and his associates for the extremely valuable work they had done in connection with the scientific exhibit. The motion was seconded by Dr. Otto H. Foerster, Milwaukee, and George M. MacKee, New York, and unanimously carried.

The chairman requested the secretary to act as chairman of a committee to handle the contribution, and appointed

Dr. Jeffrey C. Michael, Houston, Texas, and James Herbert Mitchell, Chicago, as the active collectors of the funds.

Dr. Francis Eugene Seneor, Chicago, read the chairman's address, entitled "Dermatitis Due to Woods."

Drs. Louis A. Brunsting and Daisy G. Simonsen, Rochester, Minn., presented a paper on "Cutaneous Ulcers Treated by the Sulphydryl Containing Amino Acid Cysteine." Discussed by Drs. Joseph V. Klauder, Philadelphia; John H. Stokes, Philadelphia; M. F. Engman, Jr., St. Louis, and Louis A. Brunsting, Rochester, Minn.

Dr. Adolph B. Loveman, Ann Arbor, Mich., read a paper on "Experimental Aspects of Fixed Allonal Eruption." Discussed by Drs. Samuel M. Peck, New York; Marion B. Sulzberger, New York; James Herbert Mitchell, Chicago; Walter J. Highman, New York; W. U. Rutledge, Louisville, Ky.; George Miller MacKee, New York, and Adolph B. Loveman, Ann Arbor, Mich.

Drs. George C. Andrews, Frederick W. Birkman and Richard J. Kelly, New York, presented a paper on "Recalcitrant Pustular Eruptions of the Palms and Soles." Discussed by Drs. James Herbert Mitchell, Chicago; George Miller MacKee, New York; Marion B. Sulzberger, New York; Theodore Cornbleet, Chicago; Walter J. Highman, New York; Samuel Ayres, Los Angeles; C. Ferd Lehmann, San Antonio, Texas; M. F. Engman, Jr., St. Louis; Samuel M. Peck, New York; Fred D. Weidman, Philadelphia; C. Guy Lane, Boston; Clark W. Finnerud, Chicago, and George C. Andrews, New York.

Drs. Jeffrey C. Michael and Henry O. Nicholas, Houston, Texas, presented a paper on "The Blood Lipids in Xanthoma." Discussed by Drs. Fred D. Weidman, Philadelphia; Walter J. Highman, New York, and Jeffrey C. Michael, Houston, Texas.

Drs. Max S. Wien and Marcus R. Caro, Chicago, presented a paper on "Traumatic Epithelial Cysts of the Skin." Discussed by Drs. Walter J. Highman, New York; M. J. Strauss, New Haven, Conn.; William A. Rosenberg, Chicago, and Marcus R. Caro, Chicago.

Dr. Marion B. Sulzberger, New York, read a paper on "Recent Immunologic Studies in Tobacco Hypersensitivity." Discussed by Drs. George Miller MacKee, New York; William Allen Pusey, Chicago; Walter J. Highman, New York; Paul A. O'Leary, Rochester, Minn.; W. U. Rutledge, Louisville, Ky., and Marion B. Sulzberger, New York.

THURSDAY, JUNE 15—AFTERNOON

The chairman announced that the collection on Wednesday for the Scientific Exhibit amounted to approximately \$150, which would take care of the exhibit for probably two years, and stated that any one present who had not yet contributed would be allowed that privilege at this time.

The Executive Committee reported the following nominations for officers of the section for the ensuing year: Chairman, Dr. C. Guy Lane, Boston; vice chairman, Dr. Charles C. Tomlinson, Omaha; secretary, Dr. Harry R. Foerster, Milwaukee. Nominations from the floor were called for but none were made.

Drs. Isadore Rosen, Frances Krasnow and Morris A. Lyons, New York, presented a paper on "The Lipid Partition and the Albumin-Globulin Ratio in Syphilis." Discussed by Drs. A. W. Stillians, Chicago; Theodore Cornbleet, Chicago, and Isadore Rosen, New York.

Drs. S. William Becker and M. E. Obermayer, Chicago, presented a paper on "Clinical Observations on a New Arsenical Synthetic in the Treatment of Syphilis." Discussed by Dr. John H. Stokes, Philadelphia; Chauncey D. Leake, Ph.D., San Francisco; George W. Raiziss, Ph.D., Philadelphia, and Dr. S. William Becker, Chicago.

Dr. Leo Spiegel, New York, read a paper on "Treatment of Neurosyphilis with Acetarson Given Intravenously." Discussed by Drs. Carroll S. Wright, Philadelphia; Samuel Ayres, Los Angeles, and Leo Spiegel, New York.

Drs. C. J. Lunsford, Oakland, Calif., and P. W. Day, Reprisa, Calif., presented a paper on "Experimental Inguinal Gland Transference in Human Syphilis: A Biologic Study." Discussed by Drs. M. F. Engman, Jr., St. Louis; J. Gardner Hopkins, New York, and P. W. Day, Reprisa, Calif.

Drs. J. R. Driver and Henry C. Shaw, Cleveland, presented a paper on "Divided Doses of Typhoid Vaccine in the Fever Therapy of Neurosyphilis." Discussed by Drs. Paul A. O'Leary,

Rochester, Minn.; M. O. Nelson, Tulsa, Okla.; Louis A. Brunsting, Rochester, Minn., and J. R. Driver, Cleveland.

Dr. A. Benson Cannon, New York, read a paper on "The Value of Silver Arspenamine in the Treatment of Early Syphilis: Conclusions Based on a Study of One Hundred Cases." Discussed by Drs. Earl D. Osborne, Buffalo, and A. Benson Cannon, New York.

Drs. Dudley C. Smith and William A. Brumfield, Jr., University, Va., presented a paper on "Tracing the Transmission of Syphilis: An Epidemiologic Study." Discussed by Drs. Thomas Parran, Jr., Albany, N. Y., and Dudley C. Smith, University, Va.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. C. Guy Lane, Boston; vice chairman, Dr. Charles C. Tomlinson, Omaha; secretary, Dr. Harry R. Foerster, Milwaukee.

Drs. Charles C. Tomlinson and Paul M. Bancroft, Omaha, presented a paper on "Granuloma Coccidioides—Further Observations on the Use of Antimony and Potassium Tartrate and Roentgen Therapy in Treatment: Report of an Additional Case." Discussed by Drs. George M. Lewis, New York; E. P. Zeisler, Chicago; Howard Morrow, San Francisco; Fred D. Weidman, Philadelphia, and Charles C. Tomlinson, Omaha.

Dr. John F. Madden, St. Paul, read a paper on "Generalized Angiomatosis with Particular Reference to Hereditary Hemorrhagic Telangiectasis." Discussed by Drs. Michael H. Ebert, Chicago; S. William Becker, Chicago; Samuel M. Peck, New York; James Herbert Mitchell, Chicago; Fred D. Weidman, Philadelphia, and John F. Madden, St. Paul.

Drs. Donald M. Pillsbury and George V. Kulchar, Philadelphia, presented a paper on "The Dextrose and Water Content of Normal Inflammatory Skin." Discussed by Drs. S. William Becker, Chicago; Jeffrey C. Michael, Houston, Texas, and Donald M. Pillsbury, Philadelphia.

Drs. Ethel M. Rockwood and Arthur M. Greenwood, Boston, presented a paper on "A Fatal Case of Monilial Infection of the Skin." Discussed by Drs. Cleveland J. White, Chicago; Marion B. Sulzberger, New York; George C. Andrews, New York; James Herbert Mitchell, Chicago; Everett S. Lain, Oklahoma City; Fred D. Weidman, Philadelphia, and Arthur M. Greenwood, Boston.

Drs. J. Gardner Hopkins and Beatrice M. Kesten, New York, presented a paper on "Food Ezeema." Discussed by Drs. Albert H. Rowe, Oakland, Calif.; Marion B. Sulzberger, New York; Cleveland J. White, Chicago; Louis A. Brunsting, Rochester, Minn.; Samuel Ayres, Los Angeles, and J. Gardner Hopkins, New York.

Drs. Henry E. Michelson and L. H. Winer, Minneapolis, presented a paper on "Tuberculosis of the Face." Discussed by Drs. Marion B. Sulzberger, New York; Michael H. Ebert, Chicago, and Henry E. Michelson, Minneapolis.

Dr. Paul E. Bechet, New York, read a paper on "Excessive Solar and Phototherapeutic Radiation as a Causative Factor in Certain Diseases of the Skin." Discussed by Drs. Elmore B. Tauber, Cincinnati, and Paul E. Bechet, New York.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. J. N. Baker, Montgomery, Ala.

The following papers were read as a symposium on silicosis: Dr. A. J. Lanza, New York: "The Etiology of Silicosis." Discussed by Dr. Emery R. Hayhurst, Columbus, Ohio.

Dr. R. R. Sayers, Washington, D. C.: "The Clinical Manifestations of Silicosis." Discussed by Dr. Benjamin Goldberg, Chicago.

Dr. Henry K. Pancoast, Philadelphia: "The Roentgenologic Aspect of Pneumoconiosis and Its Differential Diagnosis." Discussed by Dr. E. P. Pendergrass, Philadelphia.

In the absence of Dr. Leroy U. Gardner, Saranac Lake, N. Y., due to illness, Dr. Richard H. Jaffe, Chicago, discussed "The Pathologic Reaction in Various Pneumoconioses."

Dr. William D. McNally, Chicago: "The Silicon Dioxide Content of Lungs in Health and in Disease."

Mr. Joseph Padway, attorney, Milwaukee, addressed the meeting on the subject of "The Legal Aspects of Silicosis."

The chairman appointed as a nominating committee Drs. A. J. Lanza, New York; Thomas Parran, Jr., Albany, N. Y., and J. C. Geiger, San Francisco.

The symposium on silicosis was discussed by Drs. Robert T. Legge, Berkeley, Calif.; J. J. Singer, St. Louis; C. F. N. Schram, Beloit, Wis.; A. J. Lanza, New York; R. R. Sayers, Washington, D. C.; Henry K. Pancoast, Philadelphia, and William D. McNally, Chicago.

THURSDAY, JUNE 15—MORNING

It was voted to nominate the following for Associate Fellowship: Dr. Robert Alexander Herring, Washington, D. C., and Mr. George A. Soper, Great Neck, N. Y.

Dr. J. N. Baker, Montgomery, Ala., read the chairman's address, entitled "The Rural Tuberculosis Problem in the South."

Dr. W. H. Perkins, New Orleans, read a paper on "Teaching Preventive Practice to Students of Medicine." Discussed by Drs. M. E. Barnes, Iowa City; Fred J. Wampler, Richmond, Va.; J. V. Greenebaum, Cincinnati, and W. H. Perkins, New Orleans.

Dr. Thomas Parran, Jr., Albany, N. Y., read a paper on "Public Medical Care in New York State." Discussed by Drs. W. H. Ross, Brentwood, N. Y.; Nathan B. Van Etten, New York, and Thomas Parran, Jr., Albany, N. Y.

Dr. Thomas B. Magath, Rochester, Minn., read a paper on "The Relation of Diphylobothrium Latum Infestation to the Public Health." Discussed by Drs. Moses Barron, Minneapolis; M. W. Lyon, Jr., South Bend, Ind.; Thomas Myers, St. Paul; W. S. Leathers, Nashville, Tenn., and Thomas B. Magath, Rochester, Minn.

Drs. W. V. Evans and H. H. Rowley, Evanston, Ill., presented a paper on "Spray Residue Poisoning." Discussed by Dr. J. C. Geiger, San Francisco; Mr. J. O. Clarke, Chicago, and Drs. M. E. Barnes, Iowa City; W. S. Leathers, Nashville, Tenn., and W. V. Evans, Evanston, Ill.

Dr. Louis Schwartz, New York, read a paper on "Dermatitis in the Rubber Industry." Discussed by Drs. Earl D. Osborne, Buffalo; John G. Downing, Boston, and Louis Schwartz, New York.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. W. G. Smillie, Boston; vice chairman, Dr. John P. Koehler, Milwaukee; secretary, Dr. R. R. Sayers, Washington, D. C.; delegate, Dr. Stanley H. Osborne, Hartford, Conn.

On motion of Dr. Robert T. Legge, Berkeley, Calif., the following resolution, presented by Dr. William F. Snow, New York, was adopted:

I respectfully present the following resolution for consideration, in view of the fact that the Conference of State and Provincial Health Authorities of North America, the American Social Hygiene Association, the National Society for the Prevention of Blindness, and other agencies have recently voiced their desire to assist in concerted action to promote public interest in the prevention of congenital syphilis.

I understand that the Sections of the American Medical Association on Obstetrics, Gynecology and Abdominal Surgery, on Dermatology and Syphilology, on Pediatrics, and on Ophthalmology are considering similar actions in order to show how generally the medical profession is concerned with the cooperation of all agencies in solving this public health and welfare problem.

WHEREAS, Congenital syphilis is responsible for so much morbidity and mortality among children; and

WHEREAS, Early and effective treatment of infected pregnant women would have prevented this disease in these children in as high as 90 per cent of the cases, in addition to bringing syphilis under control in the mothers; and

WHEREAS, The diagnosis, treatment and after-care involved are no longer prohibitive in expense or time required of either the doctor or patient; be it

Resolved, That the Section on Preventive and Industrial Medicine and Public Health recommend to all agencies and individuals in a position to help, participation in promoting popular understanding and application of modern knowledge to the reduction of congenital syphilis; and be it further

Resolved, That blood examinations, including tests for syphilis, be urged for every pregnant woman at the beginning of her pregnancy.

Drs. Gaylord W. Anderson and Roderick Heffron, Boston, presented a paper on "Two Years of the Massachusetts Pneumonia Program."

Dr. Wilson G. Smillie, Boston, read a paper on "The Epidemiology of Lobar Pneumonia."

Dr. W. D. Sutliff, Boston, read a paper on "The Distribution of the Newly Classified Serologic Types of Pneumococci in Disease."

These three papers were discussed by Drs. H. A. Reimann, Minneapolis; William H. Park, New York; Maxwell Finland, Boston; M. E. Barnes, Iowa City; Gaylord W. Anderson, Boston; Wilson G. Smillie, Boston, and W. D. Sutliff, Boston.

Dr. James A. Crabtree, Nashville, Tenn., read a paper on "Tuberculosis Studies in Tennessee: Tuberculosis in the Negro as Related to Certain Conditions of Environment." Discussed by Drs. J. A. Myers, Minneapolis; John Ritter, Miami, Fla.; O. O. Miller, Louisville, Ky., and James A. Crabtree, Nashville, Tenn.

Dr. C. St. C. Guild, New York, read a paper on "Tuberculosis Among Negroes: A Discussion of the Major Problems That Complicate Its Control." Discussed by Drs. Horton R. Casparis, Nashville, Tenn.; Marie Pichel Levinson, New York; Emil Bogen, Olive View, Calif., and C. St. C. Guild, New York.

Dr. J. C. Geiger, San Francisco, read a paper on "Food Poisoning: A Report of Three Outbreaks." Discussed by Drs. John P. Kochler, Milwaukee, and J. C. Geiger, San Francisco.

SECTION ON UROLOGY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. N. G. Alcock, Iowa City.

The following papers were read as a symposium on "Excretion Urography":

Dr. W. F. Braasch, Rochester, Minn.: "The Practical Application of Intravenous Urography."

Dr. Moses Swick, New York: "Excretion Urography with Particular Reference to a New Compound, Sodium Iodohipurate."

These two papers were discussed by Drs. Ira R. Sisk, Madison, Wis.; L. T. Le Wald, New York; Thomas D. Moore, Memphis, Tenn.; W. F. Braasch, Rochester, Minn., and Moses Swick, New York.

The chairman appointed Dr. Hermon C. Bumpus, Rochester, Minn., to serve on the executive committee in the place of Dr. J. D. Barney, Boston, who was unavoidably absent.

The chairman stated that Dr. Maximilian Stern, De Land, Fla., was unable to be present to read his paper on Thursday morning, and that with the unanimous consent of the section a paper by Dr. John R. Caulk, St. Louis, could be substituted.

On motion, regularly seconded and carried, it was voted that Dr. Caulk be allowed to present his paper.

Dr. Robert H. Herbst, Chicago, read a paper on "Urography as a Guide to the Surgical Indications in Diverticula of the Urinary Bladder."

Dr. R. B. Henline, New York, read a paper on "Traumatic Injuries of the Urinary Tract: Comparative Value of Intravenous Urography and Pyelography—Diagnosis and Treatment."

These two papers were discussed by Drs. Miley B. Wesson, San Francisco; Thomas D. Moore, Memphis, Tenn.; W. E. Stevens, San Francisco; O. S. Lowsley, New York; Robert Gutierrez, New York; J. S. Eisenstaedt, Chicago; P. E. McGown, Indianapolis; Robert H. Herbst, Chicago, and R. B. Henline, New York.

Dr. Charles M. McKenna, Chicago, read a paper on "The Routine Use of Iopax in Suspected Injuries to the Kidney, Bladder and Other Urinary Organs." Discussed by Drs. G. H. Ewell, Madison, Wis.; Moses Swick, New York; A. I. Folsom, Dallas, Texas, and Charles M. McKenna, Chicago.

Drs. J. A. Hyams, New York; H. R. Kenyon, Cedarhurst, N. Y., and S. E. Kramer, Perth Amboy, N. J., presented a paper on "Urethrocytography as a Routine Diagnostic Measure in Urologic Examinations." Discussed by Drs. M. A. Nicholson, Duluth, Minn.; Robert Gutierrez, New York; Harry P. Lee, Iowa City; N. G. Alcock, Iowa City, and J. A. Hyams, New York.

THURSDAY, JUNE 15—MORNING

The following papers were read as a symposium on "Transurethral Resection and Prostatic Surgery":

Dr. N. G. Alcock, Iowa City: "A Comparison of Immediate Results in Two Equal Consecutive Series of Cases of Prostatic Resection and Surgical Prostatectomy: Chairman's Address."

Drs. Leon Herman and L. B. Greene, Philadelphia: "A Clinical Consideration of Transurethral Resection with Analyses and Studies of Results."

Drs. W. E. Lower and W. J. Engel, Cleveland: "Individualizing the Prostatic Patient in the Selection of Treatment."

These three papers were discussed by Drs. Hermon C. Bumpus, Rochester, Minn.; A. I. Folsom, Dallas, Texas; Irvin S. Koll, Chicago; Herman L. Kretschmer, Chicago; H. W. E. Walther, New Orleans; W. J. Engel, Cleveland, and N. G. Alcock, Iowa City.

Dr. O. S. Lowsley, New York, read a paper on "A Review of the Prostatic Problem Based on Developments of the Past Three Years in This Field of Surgery." Discussed by Drs. Omar F. Elder, Atlanta, Ga.; J. R. Dillon, San Francisco; A. I. Folsom, Dallas, Texas; N. G. Alcock, Iowa City, and O. S. Lowsley, New York.

Dr. John R. Caulk, St. Louis, read a paper on "The Influence of the Type of Current on the Postoperative Complications in Transurethral Surgery."

Dr. C. W. Collings, New York, read a paper on "The Removal of Tissue at the Bladder Neck for the Relief of Prostatic Obstruction."

These two papers were discussed by Drs. F. E. B. Foley, St. Paul; T. J. Kirwin, New York; C. H. deT. Shivers, Atlantic City, N. J.; Abraham Ravich, Brooklyn; John R. Caulk, St. Louis, and C. W. Collings, New York.

Drs. W. N. Wishard, Jr., H. G. Hamer and H. O. Mertz, Indianapolis, presented a paper on "A Presentation of a Method for Local Infiltration Anesthesia of the Prostate Preliminary to Prostatic Resection." Discussed by Drs. G. J. Thompson, Rochester, Minn.; H. M. Stang, Eau Claire, Wis.; Julius Frischer, Kansas City, Mo.; George H. Ewell, Madison, Wis.; J. A. Hyams, New York, and W. N. Wishard, Jr., Indianapolis.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. Harry Culver, Chicago; vice chairman, Dr. W. M. Kearns, Milwaukee; secretary, Dr. J. H. Morrissey, New York; delegate, Dr. H. W. E. Walther, New Orleans; alternate, Dr. Henry L. Sanford, Cleveland.

The following papers were read as a symposium on "The Pyelitis of Pregnancy":

Drs. N. S. Heaney, H. L. Kretschmer and E. A. Ockuly, Chicago: "A Pyelographic Study of the Effects of Pregnancy on the Kidneys and Ureters."

Dr. E. M. Randall, Rochester, Minn.: "The Postpartum Bladder."

These two papers were discussed by Drs. F. H. Falls, Chicago; Vincent J. O'Connor, Chicago; William E. Stevens, San Francisco; W. E. Heller, Fargo, N. D.; G. C. Prather, Boston; N. S. Heaney, Chicago, and L. M. Randall, Rochester, Minn.

Dr. E. G. Crabtree, Boston, read a paper on "The Relation of Pregnancy Changes and Infections to Recurrence of Infection in Subsequent Pregnancies."

Dr. H. W. E. Walther, New Orleans, read a paper on "Postpartal Pyelonephritis."

These two papers were discussed by Drs. A. I. Folsom, Dallas, Texas; G. C. Prather, Boston; Anson L. Clark, Rochester, Minn.; J. I. Hoffbauer, Baltimore; E. G. Crabtree, Boston, and H. W. E. Walther, New Orleans.

Dr. H. D. Furniss, New York, read a paper on "Pyelitis and Pyelonephritis in Pregnancy—Studies with Reference to the Persistence of Symptoms Following Delivery. Treatment: Indications and Results."

Dr. D. K. Rose, St. Louis, read a paper on "Treatment of Certain Cases of Pyelitis of Pregnancy Without the Use of the Urethral Catheter."

Dr. Harry P. Lee, Iowa City, read a paper on "The Effect of Pregnancy on the Urinary Tract."

These three papers were discussed by Drs. W. E. Stevens, San Francisco; R. M. Nesbit, Ann Arbor, Mich.; M. W.

Sherwood, Milwaukee; John K. Ormond, Detroit; J. I. Hofbauer, Baltimore; J. S. Lewis, Youngstown, Ohio; F. H. Falls, Chicago; William P. Herbst, Washington, D. C.; Abraham Ravich, Brooklyn; E. G. Crabtree, Boston; G. C. Prather, Boston; W. J. Wallace, Oklahoma City, and Robert Gutierrez, New York.

The chairman stated that the section had had the largest attendance in four years, and extended the thanks of the section to the Milwaukee urologists for their splendid cooperation and hospitality.

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:15 by the chairman, Dr. W. Barnett Owen, Louisville, Ky.

Dr. Myron O. Henry, Minneapolis, read a paper on "Intra-capsular Fractures of the Hip: A New Device for Lateral Osteosynthesis." Discussed by Drs. John Hunt Shephard, San Jose, Calif.; Chester C. Schneider, Milwaukee; John W. Powers, Milwaukee; W. B. Carrell, Dallas, Texas; Laurence Jones, Kansas City, Mo., and Myron O. Henry, Minneapolis.

Dr. Garry de N. Hough, Jr., Springfield, Mass., read a paper on "Epinephrine and Pilocarpine in the Treatment of Progressive Pseudohypertrophic Muscular Dystrophy." Discussed by Drs. Arthur Steindler, Iowa City; H. B. Thomas, Chicago; Philip Lewin, Chicago, and Garry de N. Hough, Jr., Springfield, Mass.

Dr. Henry W. Meyerding, Rochester, Minn., and Dr. R. J. Mroz, Rockford, Ill., read a paper on "Tuberculosis of the Greater Trochanter." Discussed by Drs. Frederick C. Kidner, Detroit; C. A. Stone, St. Louis; Arthur Steindler, Iowa City, and Henry W. Meyerding, Rochester, Minn.

Dr. W. R. MacAusland, Boston, read a paper on "Knee Joint Arthroplasty."

Dr. Fred H. Albee, New York, read a paper on "Original Features of Arthroplasty of the Hip and Knee."

These two papers were discussed by Drs. W. Barnett Owen, Louisville, Ky.; J. S. Speed, Memphis, Tenn.; Edwin W. Ryerson, Chicago; Fred H. Albee, New York, and W. R. MacAusland, Boston.

Dr. Burt G. Chollet, Toledo, Ohio, read a paper on "Relapsed or Resistant Club Feet of Early Childhood." Discussed by Drs. Harold A. Soffield and Frank G. Murphy, Chicago, and Dr. Burt G. Chollet, Toledo, Ohio.

Drs. George A. Williamson and Wallace H. Cole, St. Paul, presented a paper on "Chronic Recurrent Dislocation of the Patella." Discussed by Drs. Herman C. Schumm, Milwaukee; Paul W. Giessler, Minneapolis; James A. Dickson, Cleveland; Edwin W. Ryerson, Chicago; Fred H. Albee, New York; C. A. Stone, St. Louis; H. E. Cooper, Peoria, Ill., and George A. Williamson, St. Paul.

THURSDAY, JUNE 15—MORNING

Dr. J. Warren White, Greenville, S. C., read a paper on "Use of Autogenous Bone Pin Through Acromion into Humeral Head in Shoulder Arthrodeses." Discussed by Drs. Robert E. Burns, Madison, Wis., and Emil D. W. Hauser, Chicago.

Dr. Paul N. Jepson, Philadelphia, read a paper on "Traumatic Backache."

Dr. Ralph K. Ghormley, Rochester, Minn., read a paper on "Low Back Pain with Especial Reference to the Importance of the Articular Facets."

These two papers were discussed by Drs. Henry W. Meyerding, Rochester, Minn.; Robert B. Osgood, Boston; Lewis Clark Wagner, New York; Paul N. Jepson, Philadelphia, and Ralph K. Ghormley, Rochester, Minn.

Dr. W. Barnett Owen, Louisville, Ky., read the chairman's address, entitled "Ununited Fractures of the Shaft of the Humerus."

Dr. Marion N. Gibbons, Cleveland, read a paper on "Roentgenographic Observations on the Course of Aberrant Ossification in the Foot." Discussed by Drs. Arthur Steindler, Iowa City; R. Plato Schwartz, Rochester, N. Y.; Marcus H. Hobart, Evanston, Ill.; J. S. Speed, Memphis, Tenn., and Marion N. Gibbons, Cleveland.

Dr. Frederick C. Kidner, Detroit, read a paper on "Pre-hallux as a Cause of Flatfoot: Operative Correction." Dis-

cussed by Drs. Charles W. Peabody, Detroit; Edwin W. Ryerson, Chicago, and Frederick C. Kidner, Detroit.

Dr. Joseph A. Freiberg, Cincinnati, read a paper on "Early Diagnosis and Treatment of Congenital Dislocation of the Hip." Discussed by Drs. John L. Porter, Evanston, Ill.; Ralph K. Ghormley, Rochester, Minn.; W. P. Blount, Milwaukee, and Joseph A. Freiberg, Cincinnati.

FRIDAY, JUNE 16—MORNING

The following officers were elected: chairman, Dr. J. S. Speed, Memphis, Tenn.; vice chairman, Dr. R. D. Schrock, Omaha; delegate, Dr. Henry W. Meyerding, Rochester, Minn.; alternate, Dr. W. Barnett Owen, Louisville, Ky.; secretary, Dr. Fremont A. Chandler, Chicago.

The report of the Committee on Certification of Specialists, read by Dr. Henry W. Meyerding, Rochester, Minn., was adopted and the committee was continued.

Proper memorial resolutions were ordered drawn up concerning the deaths of the following members of the section: Drs. Russell A. Hibbs, New York; Ansel G. Cook, Hartford, Conn.; Emil Geist, Minneapolis; Nathaniel Allison, Chicago, and Edward A. Rich, Tacoma, Wash., also Sir Robert Jones, England.

Dr. W. K. West, Oklahoma City, read a paper on "The Treatment of Fractures of the Shaft of the Tibia and Fibula, Using Skeletal Traction." Discussed by Drs. F. J. Gaenslen, Milwaukee; W. B. Carrell, Dallas, Texas; D. H. Levinthal, Chicago, and W. K. West, Oklahoma City.

Dr. Edwin W. Ryerson, Chicago, read a paper on "Osteotomy for Flexion Deformity at the Hip Due to Anterior Poliomyelitis." Discussed by Drs. J. S. Speed, Memphis, Tenn.; John O. Dieterle, Milwaukee, and Edwin W. Ryerson, Chicago.

Dr. Clay Ray Murray, New York, read a paper on "Fracture Healing: Its Influence on the Choice of Treatment Methods."

Dr. J. Albert Key, St. Louis, read a paper on "The Effect of a Local Calcium Depot on Osteogenesis and Healing of Fractures."

These two papers were discussed by Drs. F. J. Gaenslen, Milwaukee; Edward L. Compere, Chicago; R. D. Schrock, Omaha; Clay Ray Murray, New York, and J. Albert Key, St. Louis.

Dr. H. Winnett Orr, Lincoln, Neb., read a paper on "The Albee Bone Graft and the Winnett Orr Method of Postoperative Care for the Immediate Treatment of Compound Fractures." Discussed by Drs. E. D. McBride, Oklahoma City, and H. Winnett Orr, Lincoln, Neb.

Dr. D. M. Bosworth, New York, read a paper on "Subperiosteal Resection of the Tibial Shaft in Osteomyelitis." Discussed by Drs. D. B. Phemister, Chicago; J. E. M. Thomson, Lincoln, Neb., and D. M. Bosworth, New York.

Dr. Edson B. Fowler, Chicago, read a paper on "Stiff, Painful Shoulders, Exclusive of Tuberculosis and Other Infections." Discussed by Drs. Edwin W. Ryerson, Chicago; F. J. Gaenslen, Milwaukee, and Edson B. Fowler, Chicago.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:10 by the chairman, Dr. Curtice Rosser, Dallas, Texas.

The chairman announced the substitution on the Executive Committee of Dr. Sara M. Jordan, Boston, for Dr. G. B. Eusterman, Rochester, Minn., and Dr. Louis A. Buie, Rochester, Minn., for Dr. Dudley A. Smith, San Francisco.

Dr. Collier F. Martin, Philadelphia, read a paper on "Stricture of the Rectum: Some of Its Problems." Discussed by Drs. Clyde W. Morter, Milwaukee; Herbert T. Hayes, Houston, Texas; A. A. Goldsmith, Chicago; M. H. Streicher, Chicago; E. Jay Clemons, Los Angeles; John L. Jelks, Memphis, Tenn., and Collier F. Martin, Philadelphia.

Dr. Frank G. Yeomans, New York, read a paper on "Management of Advanced Carcinoma of the Gastro-Intestinal Tract." Discussed by Drs. George E. Binkley, New York; Harry H. Bowing, Rochester, Minn.; Louis J. Hirschman, Detroit, and Frank G. Yeomans, New York.

Drs. W. A. Fansler and James Kerr Anderson, Minneapolis, presented a paper on "A Plastic Operation for Certain Types of Hemorrhoids." Discussed by Drs. Clement L. Martin, Chicago; Louis J. Hirschman, Detroit, and W. A. Fansler, Minneapolis.

Drs. James F. Weir and Waltman Walters, Rochester, Minn., presented a paper on "Preoperative and Postoperative Management of Diseases of the Upper Part of the Digestive Tract." Discussed by Drs. Walter L. Palmer, Chicago; Russell L. Haden, Cleveland; Horace W. Soper, St. Louis; Waltman Walters, Rochester, Minn.; R. R. Best, Omaha; A. L. Levin, New Orleans, and Frank Smithies, Chicago.

Dr. Moses Paulson, Baltimore, read a paper on "The Present Status of Chronic Ulcerative Colitis with Special Reference to Etiology." Discussed by Drs. Sara M. Jordan, Boston; Frank Smithies, Chicago; Frank H. Lahey, Boston; M. H. Streicher, Chicago; John L. Jelks, Memphis, Tenn.; Louis A. Buie, Rochester, Minn., and Moses Paulson, Baltimore.

Drs. Louis A. Buie and J. A. Borgen, Rochester, Minn., presented a paper on "Chronic Ulcerative Colitis: Additional Proof of Its Systemic Origin." Discussed by Drs. Horace W. Soper, St. Louis; Benjamin Jablons, New York; E. Jay Clemons, Los Angeles, and Louis A. Buie, Rochester, Minn.

THURSDAY, JUNE 15—AFTERNOON

Dr. Curtice Rosser, Dallas, Texas, read the chairman's address, entitled, "Current Questions in Proctology."

Dr. Albert F. R. Andresen, Brooklyn, read a paper on "Migraine—An Allergic Phenomenon." Discussed by Drs. Albert H. Rowe, Oakland, Calif.; Harry B. Wilmer, Philadelphia; Russel S. Boles, Philadelphia; Misch Casper, Louisville, Ky.; C. Ulysses Moore, Portland, Ore., and Albert F. R. Andresen, Brooklyn.

Dr. Walter L. Palmer, Chicago, read a paper on "Fundamental Difficulties in the Treatment of Gastric and Duodenal Ulcer." Discussed by Drs. Sidney A. Portis, Chicago; Clarence F. G. Brown, Chicago; Robert Kapsinow, Lafayette, La.; G. A. Hendon, Louisville, Ky.; Sara M. Jordan, Boston; A. L. Levin, New Orleans, and Walter L. Palmer, Chicago.

Dr. S. Allen Wilkinson, Jr., Boston, read a paper on "Gastric Acidity in Thyroid Dysfunction." Discussed by Drs. Ralph C. Brown, Chicago, and S. Allen Wilkinson, Jr., Boston.

Dr. Seale Harris, Birmingham, Ala., read a paper on "Hyperinsulinism—A Disease Entity: A Résumé of the Etiology, Pathology, Symptoms, Diagnosis, Prognosis and Treatment of Spontaneous Insulogenic Hypoglycemia." Discussed by Drs. Russell M. Wilder, Rochester, Minn.; Henry J. John, Cleveland; Géza de Takáts, Chicago, and Seale Harris, Birmingham, Ala.

Dr. Maurice B. Strauss, Boston, read a paper on "The Digestive Tract and Diet in Anemia." Discussed by Drs. Cyrus C. Sturgis, Ann Arbor, Mich., and Maurice B. Strauss, Boston.

Drs. Adolph M. Hutter and William S. Middleton, with the collaboration of Harry Steenbock, Madison, Wis., presented a paper on "Vitamin B Deficiency and the Atrophic Tongue." Discussed by Drs. Frank D. Gorham, St. Louis, and William S. Middleton, Madison, Wis.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. A. F. R. Andresen, Brooklyn; vice chairman, Dr. Walter A. Fansler, Minneapolis; secretary, Dr. H. L. Bockus, Philadelphia; delegate, Dr. Descum C. McKenney, Buffalo; alternate, Dr. Sara M. Jordan, Boston.

The Secretary read the following communication to the section, dated June 13:

The American Proctologic Society respectfully requests that the section name three members to cooperate with a committee already appointed by the society, to wit: Dr. Curtice Rosser, Dallas, Texas, chairman; Dr. Louis A. Buie, Rochester, Minn.; Dr. Frank G. Runyon, Reading, Pa., which complete committee shall keep in contact with the activities of the Council on Medical Specialties in connection with possible certification of proctologists, and report their recommendations to the society and to the section in one year.

CURTICE ROSSER.

President, American Proctologic Association.

On motion of Dr. William A. Swalm, Philadelphia, seconded by Dr. Louis J. Hirschman, Detroit, the following resolution was adopted:

WHEREAS, The American Gastro-Enterological Association and the American Proctologic Society have each appointed committees of three members with power to cooperate with similar committees from this section in the formation of national examining boards in their respective specialties; and

WHEREAS, Each of these societies is the only national organization recognized in its special field and therefore the only organization authorized to assist in the formation of such a board; therefore be it

Resolved, That the retiring chairman of this section and his successor in office shall each appoint a committee of three members in his respective specialty, such committees to have full power to cooperate with the committees of the American Gastro-Enterological Association and the American Proctologic Society above mentioned in the formation of national boards and to act as representatives of this section on such boards when organized.

The chairman appointed the following members in his specialty: Dr. Louis J. Hirschman, Detroit; Dr. W. A. Fansler, Minneapolis, and Dr. Descum C. McKenney, Buffalo.

The following papers were read as a symposium on "Abdominal Pain":

Dr. Emanuel Libman, New York: "Individual Sensitivity to Pain and Radiations of Pain."

Dr. Walter C. Alvarez, Rochester, Minn.: "Mechanism of Abdominal Pain of Visceral Origin."

Dr. F. M. Pottenger, Monrovia, Calif.: "Clinical Aspects of Abdominal Pain of Visceral Origin."

Dr. John Berton Carnett, Philadelphia: "Pain and Tenderness of the Abdominal Wall."

Dr. Louis J. Hirschman, Detroit: "Anorectal Pain and Its Clinical Significance."

These five papers were discussed by Drs. Russell S. Boles, Philadelphia; Burrill B. Crohn, New York; Fred M. Smith, Iowa City; Elmer L. Eggleston, Battle Creek, Mich.; William J. Kerr, San Francisco; Descum C. McKenney, Buffalo; William Bates, Philadelphia; Seale Harris, Birmingham, Ala.; H. L. Bockus, Philadelphia; Emanuel Libman, New York; Walter C. Alvarez, Minneapolis; F. M. Pottenger, Monrovia, Calif.; John Berton Carnett, Philadelphia, and Louis J. Hirschman, Detroit.

On motion of Dr. Elmer L. Eggleston, Battle Creek, Mich., duly seconded, the following motion was adopted:

Those of us who have been so fortunate as to visit the Scientific Exhibition sponsored by this section must recognize that a very great amount of thought and work has been demanded of the committee; therefore, I wish to move that we express our appreciation to Dr. A. H. Aaron, the chairman of this committee, for the satisfactory work accomplished.

SECTION ON RADIOLOGY

WEDNESDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. George W. Grier, Pittsburgh.

Dr. W. E. Chamberlain, Philadelphia, was appointed to serve on the Executive Committee in place of Dr. Arthur W. Erskine, Cedar Rapids, Iowa, who was absent.

Dr. George W. Grier, Pittsburgh, read the chairman's address, entitled "The Role of the Radiologist in the Treatment of Cancer."

Drs. Max Ballin, Plinn F. Morse and William A. Evans, Detroit, presented a paper on "Skeletal Pathology of Endocrine and Metabolic Origin." Discussed by Drs. Edward L. Compere, Chicago; E. R. Witwer, Detroit; Henry K. Pancoast, Philadelphia, and Plinn F. Morse, Detroit.

Drs. Leo G. Rigler and Frederick B. Exner, Minneapolis, presented a paper on "The Latent Period in the Roentgen Diagnosis of Pulmonary Tuberculosis." Discussed by Dr. J. A. Myers, Minneapolis.

Dr. H. Kennon Dunham, Cincinnati, read a paper on "Proper Interpretation of Chest Exposed, with Special Reference to Differential Diagnosis of Pulmonary Tuberculosis." Discussed by Drs. Henry K. Pancoast, Philadelphia, and H. Kennon Dunham, Cincinnati.

Dr. David Steel, Cleveland, read a paper on "The Roentgenologic Diagnosis of Cardiac Aneurysms." Discussed by

Drs. Fred J. Hodges, Ann Arbor, Mich., and David Steel, Cleveland.

Dr. Samuel Brown, Cincinnati, read a paper on "Atypical Forms of Pleurisy: A Roentgenologic Study." Discussed by Drs. Moses Salzer, Cincinnati; Leon T. Le Wald, New York; John W. Pierson, Baltimore; Leo G. Rigler, Minneapolis, and Samuel Brown, Cincinnati.

THURSDAY, JUNE 15—AFTERNOON

Dr. Harold Swanberg, Quincy, Ill., read a paper on "Cholecystographic Study of the Bile Ducts." Discussed by Dr. John W. Pierson, Baltimore.

Dr. Byron H. Jackson, Scranton, Pa., read a paper on "Roentgenologic Observations in Certain Chronic Gastric Conditions Which Are Completely Relieved by a Special Diet." Discussed by Drs. J. William White, Scranton, Pa.; E. P. Pendergrass, Philadelphia; W. E. Chamberlain, Philadelphia; Harry A. Olin, Chicago; E. L. MacQuiddy, Omaha; John T. Murphy, Toledo, Ohio, and Byron H. Jackson, Scranton, Pa.

Dr. E. L. Jenkinson, Chicago, read a paper on "The Importance of the Size of the Stomach and Stoma in Gastro-Enterostomies." Discussed by Drs. B. R. Kirklin, Rochester, Minn., and E. P. Pendergrass, Philadelphia.

Dr. B. R. Kirklin, Rochester, Minn., read a paper on "Persisting Errors in the Technique of Oral Cholecystography: A Procedure Designed to Avoid Them." Discussed by Drs. Walter L. Palmer, Chicago; Adolph Hartung, Chicago; Paul C. Hodges, Chicago; Harry A. Olin, Chicago, and B. R. Kirklin, Rochester, Minn.

Drs. William H. Stewart and H. Earle Illick, New York, presented a paper entitled "Comments on the Roentgen Diagnosis of Carcinoma at the Cardia." Discussed by Drs. B. R. Kirklin, Rochester, Minn.; E. P. Pendergrass, Philadelphia; Maurice I. Kaplan, Chicago; Leo G. Rigler, Minneapolis, and H. Earle Illick, New York.

Drs. Daniel M. Clark and Milton J. Geyman, Santa Barbara, Calif., presented a paper on "Roentgen Evidence of Healing in Duodenal Ulcer." Discussed by Drs. George W. Grier, Pittsburgh; B. R. Kirklin, Rochester, Minn., and Daniel M. Clark, Santa Barbara, Calif.

FRIDAY, JUNE 16—AFTERNOON

The following officers were elected: chairman, Dr. A. U. Desjardins, Rochester, Minn.; vice chairman, Dr. Amédée Granger, New Orleans; secretary, Dr. John T. Murphy, Toledo, Ohio.

Drs. George W. Holmes, Boston; John W. Pierson, Baltimore, and Lyell C. Kinney, San Diego, Calif., were appointed to represent the section on the National Qualifying Board of Radiology.

Dr. A. U. Desjardins, Rochester, Minn., was appointed to serve on the Executive Committee in place of Dr. Henry K. Pancoast, Philadelphia, who was called home.

Dr. Carl L. Gillies, Cedar Rapids, Iowa, read a paper on "Torus Fractures of the Lower Extremity of the Forearm in Children." Discussed by Dr. Paul C. Hodges, Chicago.

Drs. Fred J. Hodges and Carleton B. Peirce, Ann Arbor, Mich., presented a paper on "A Method of Undergraduate Teaching in Clinical Roentgenology." Discussed by Drs. W. E. Chamberlain, Philadelphia, and Fred J. Hodges, Ann Arbor, Mich.

Dr. Douglas Quick, New York, read a paper on "Radiation in Primary Operable Breast Cancer." Discussed by Drs. F. W. O'Brien, Boston; U. V. Portmann, Cleveland, and Douglas Quick, New York.

Dr. A. U. Desjardins, Rochester, Minn., read a paper on "Radiotherapy as a Method of Identifying Certain Varieties of Tumor." Discussed by Drs. Norbert Enzer, Milwaukee, and A. U. Desjardins, Rochester, Minn.

Dr. Albert Soiland, Los Angeles, read a paper on "Comments on the Higher X-Ray Voltages."

Dr. U. V. Portmann, Cleveland, read a paper on "Procedures for the Treatment of Myelogenous Leukemia." Discussed by Drs. A. U. Desjardins, Rochester, Minn., and U. V. Portmann, Cleveland.

Dr. Charles Goosmann, Cincinnati, read a paper on "Some Mistakes in the Microscopic Diagnosis of Tumors." Discussed

by Drs. W. E. Chamberlain, Philadelphia; A. U. Desjardins, Rochester, Minn.; Douglas Quick, New York, and Charles Goosmann, Cincinnati.

SECTION ON MISCELLANEOUS TOPICS

Sessions on Anesthesia

WEDNESDAY, JUNE 14—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. Albert H. Miller, Providence, R. I.

The chairman filled the vacancies on the Executive Committee by appointing Dr. Ralph M. Waters, Madison, Wis., and Dr. John S. Lundy, Rochester, Minn., to take the place of those not present.

Dr. John L. Emmett, Rochester, Minn., read a paper on "Subarachnoid Injections of Procaine: The Quantitative Effects of Clinical Doses on Sensory, Sympathetic and Motor Nerves." Discussed by Drs. Nelson W. Barker, Rochester, Minn.; Frank A. Kelly, Detroit, and John L. Emmett, Rochester, Minn.

Dr. Frank W. Marvin, Boston, read a paper on "The Present Status of Various Spinal Anesthetics and Their Clinical Usefulness." Discussed by Drs. Floyd T. Romberger, La Fayette, Ind.; Frank A. Kelly, Detroit; M. L. Axelrod, Cleveland, and Frank W. Marvin, Boston.

Drs. John S. Lundy, Hiram E. Essex and James W. Kernohan, Rochester, Minn., presented a paper on "Experiments with Anesthetics: IV. Lesions of the Spinal Cord." Discussed by Drs. Hale Haven, Chicago; James W. Kernohan, Rochester, Minn., and Hiram E. Essex, Rochester, Minn.

Dr. Henry S. Ruth, Philadelphia, read a paper on "Diagnostic, Prognostic and Therapeutic Nerve Blocks." Discussed by Drs. Paul G. Flothow, Seattle; Géza de Takáts, Chicago, and Henry S. Ruth, Philadelphia.

Dr. Lincoln S. Sise, Boston, read a paper on "Tribrom-Ethanol. Intratracheal and Regional Anesthesia in Abdominal Operations." Discussed by Drs. Frank H. Lahey, Boston, and Lincoln S. Sise, Boston.

Dr. Paul M. Wood, New York, read a paper on "The Present Status of Preliminary Medication." Discussed by Drs. Willard Bartlett, Jr., St. Louis; M. L. Axelrod, Cleveland; Ralph M. Waters, Madison, Wis., and Paul M. Wood, New York.

THURSDAY, JUNE 15—MORNING

Dr. Albert H. Miller, Providence, R. I., read the chairman's address, entitled "Organization of the Anesthesia Service of the General Hospital."

Drs. S. Goldschmidt, Isidor S. Ravdin, Baldwin Lucke, G. P. Muller and C. G. Johnston, Philadelphia, presented a paper on "Divinyl Ether." Discussed by Drs. Ralph M. Waters, Madison, Wis.; Henry S. Ruth, Philadelphia; Walter Meek, Madison, Wis.; Chauncey D. Leake, San Francisco; Hiram E. Essex, Rochester, Minn.; John S. Lundy, Rochester, Minn.; James G. Poe, Dallas, Texas, and Isidor S. Ravdin, Philadelphia.

Dr. Chauncey D. Leake, San Francisco, read a paper on "The Role of Pharmacology in the Development of Ideal Anesthesia." Discussed by Dr. M. H. Seevers, Madison, Wis.

Dr. Isabella C. Herb, Hubbard Woods, Ill., read a paper on "The Present Status of Ethylene." Discussed by Drs. Arthur Dean Bevan, Chicago, and Isabella C. Herb, Hubbard Woods, Ill.

Dr. Frank J. Murphy, Detroit, read a paper on "The Present Status of Nitrous Oxide, Especially Its Use in Connection with Intratracheal Anesthesia." Discussed by Drs. Carl Henry Davis, Milwaukee; Carl B. Davis, Chicago; Isabella C. Herb, Hubbard Woods, Ill., and James G. Poe, Dallas, Texas.

Dr. James G. Poe, Dallas, Texas, read a paper on "The Use of Carbon Dioxide in Anesthesia." Discussed by Drs. Ralph M. Waters, Madison, Wis.; Paul M. Wood, New York, and James G. Poe, Dallas, Texas.

On motion of Dr. Ralph M. Waters, Madison, Wis., seconded by Dr. Lincoln F. Sise, Boston, the following resolution was adopted:

Resolved, That the secretary address a letter to the secretary of the Council on Scientific Assembly, expressing appreciation of the privilege of holding the sessions on anesthesia in the Section on Miscellaneous Topics and earnestly requesting that the sessions on anesthesia and allied topics be continued at the 1934 session of the American Medical Association.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Milwaukee Session attracted a great deal of interest. Twelve sections of the Scientific Assembly cooperated with group exhibits, with thirty-seven individuals reading papers before sections who also had exhibits on the same subjects in the Scientific Exhibit.

There were four special exhibits authorized by the Board of Trustees:

The exhibit on poliomyelitis, which was a cooperative undertaking by the Committee on Scientific Exhibit with the United States Public Health Service and six sections of the Scientific Assembly, was shown for the second year. The exhibit occupied seven booths, in which demonstrations were given continuously throughout the week. In a space adjoining the exhibit, motion pictures on poliomyelitis were run continuously. The pamphlet distributed last year was revised and rewritten and given out to visitors. The committee in charge of the exhibit consisted of Michael Hoke, Warm Springs, Ga.; James P. Leake, Washington, D. C.; Arthur T. Legg, Boston; William H. Park, New York; John Ruhrah, Baltimore; James D. Trask, New Haven, Conn., and Ralph C. Williams, chairman, Washington, D. C. An advisory committee representing various sections of the Scientific Assembly was composed of the following: Section on Practice of Medicine, Thomas McCrae, Philadelphia; Section on Pediatrics, William P. Lucas, San Francisco; Section on Pathology and Physiology, Ludvig Hektoen, Chicago; Section on Nervous and Mental Diseases, Louis J. Pollock, Chicago; Section on Preventive and Industrial Medicine and Public Health, Albert J. Chesley, Minneapolis; Section on Orthopedic Surgery, Frederick J. Gaenslen, Milwaukee. Demonstrators in charge of different portions of the exhibit included John Ruhrah, Baltimore; S. D. Kramer, Brooklyn; James D. Trask, New Haven; Josephine B. Neal, New York; Jean Macnamara, Melbourne, Australia; Arthur T. Legg, Boston; Michael Hoke, Warm Springs, Ga., and Janet B. Merrill, Boston.

The special exhibit on cancer, continued for the second year, was in charge of a committee composed of Max Cutler, Chicago, R. S. Ferguson, New York, and Frank W. Hartman, chairman, Detroit, assisted by the following demonstrators: Charles J. Sutro, New York; R. S. Ferguson, New York; Grant E. Ward, Baltimore, and Max Cutler, Chicago. A continuous program of motion pictures on cancer was carried on in connection with the exhibit, and a pamphlet printed for the occasion was distributed to visitors.

The special exhibit on circulation of blood in the capillaries was given for the first time this year under the supervision of a committee composed of Gilbert H. Marquardt, Chicago, and Irving Sherwood Wright, New York, chairman, assisted by the following demonstrators: William J. Kerr, Stacy R. Mettier and R. McCalla, all of San Francisco; George E. Brown, Rochester, Minn., and A. Wilbur Duryee, New York. A continuous motion picture program on capillary circulation was run in conjunction with the exhibit. These films were made by Eliot R. Clark, Philadelphia.

The fresh tissue demonstrations, which have been an annual feature of the Scientific Exhibit for many years was presented under the direction of Norbert Enzer, Milwaukee. Prominent pathologists from various parts of the country assisted in the demonstrations of a large amount of necropsy material continuously throughout the week. The following were included among the demonstrators in this exhibit: Norbert Enzer, Otto Saphir and associates of Michael Reese Hospital, Chicago; Richard H. Jaffe and associates of Cook County Hospital, Chicago; B. S. Benjamin, Milwaukee, and John Grill, Milwaukee County Hospital, Milwaukee.

The Section on Practice of Medicine included in its group eight exhibits, one of which received a gold medal and one a certificate of merit. The section sponsored a motion picture program in connection with its exhibit and cooperated in the symposium on industrial medicine and in the special exhibit on poliomyelitis. The committee in charge was composed of James H. Austin, Philadelphia; Eugene S. Kilgore, San Francisco, and L. G. Rowntree, chairman, Philadelphia.

The Section on Obstetrics, Gynecology and Abdominal Surgery, under the direction of a committee composed of Carl Henry Davis, Milwaukee, Norman F. Miller, Ann Arbor, Mich., and E. D. Plass, chairman, Iowa City, sponsored a symposium on female genital cancer.

The Section on Ophthalmology, besides its exhibits, sponsored a motion picture program. The committee in charge was composed of Thomas D. Allen, Chicago; Edward R. Ryan, Milwaukee, and Parker Heath, chairman, Detroit.

The Section on Laryngology, Otology and Rhinology, with a committee consisting of William E. Grove, Milwaukee, Gordon F. Harkness, Davenport, Iowa, and Austin A. Hayden, chairman, Chicago, showed a large number of motion pictures in an area adjoining the exhibits of the section.

The Section on Pediatrics sponsored eight exhibits, to one of which was given a certificate of merit. The section cooperated with the special exhibit on poliomyelitis. The committee in charge consisted of Charles F. McKhann, Boston; M. G. Peterman, Milwaukee, and F. Thomas Mitchell, chairman, Memphis, Tenn.

The Section on Nervous and Mental Diseases, under a committee composed of Earl D. Bond, Philadelphia, Groves B. Smith, Godfrey, Ill., and Thomas J. Heldt, chairman, Detroit, had three exhibits on various topics.

The Section on Dermatology and Syphilology showed twelve exhibits, besides participating in the symposium on the history of dermatology and in the symposium on occupational dermatoses. The latter was a contribution by the section to the symposium on industrial medicine. A certificate of merit was given to one exhibit in this section group. The committee in charge of the exhibits was composed of Clark W. Finnerud, Chicago; Robert L. Gilman, Philadelphia; Hamilton Montgomery, Rochester, Minn.; Lester M. Wieder, Milwaukee, and Fred D. Weidman, chairman, Philadelphia.

The Section on Preventive and Industrial Medicine and Public Health showed three exhibits, to one of which was given a silver medal, besides cooperating in the symposium on industrial medicine and with the special exhibit on poliomyelitis. The committee in charge was composed of Alice Hamilton, Boston; Theodore L. Squier, Milwaukee, and Paul A. Davis, chairman, Akron, Ohio.

The Section on Urology showed nine exhibits, to one of which was given a gold medal. The exhibit was in charge of a committee as follows: F. E. B. Foley, St. Paul; Moses Swick, New York, and R. S. Ferguson, chairman, New York.

The Section on Orthopedic Surgery, with a committee composed of Paul N. Jepson, Philadelphia, J. T. O'Ferrall, New Orleans, Herman C. Schumm, Milwaukee, and E. B. Mumford, chairman, Indianapolis, showed three exhibits, one of which received a bronze medal. The section also cooperated with the special exhibit on poliomyelitis.

The Section on Gastro-Enterology and Proctology had eleven exhibits, besides a motion picture program which was run continuously throughout the week. The committee in charge was composed of A. F. R. Andresen, Brooklyn; W. A. Fansler, Minneapolis, and A. H. Aaron, chairman, Buffalo.

The Section on Radiology, besides cooperating in the symposium on industrial medicine, presented five exhibits. The committee in charge was composed of H. B. Podlasky, Milwaukee; Leroy Sante, St. Louis, and James T. Case, chairman, Chicago.

The symposium on industrial medicine received contributions from the Section on Practice of Medicine, the Section on Dermatology and Syphilology, the Section on Preventive and Industrial Medicine and Public Health and the Section on Radiology. It included six exhibits, to one of which was given a bronze medal.

Besides the four special exhibits and seventy-seven exhibits under the auspices of the various sections of the Scientific Assembly, there were seventeen exhibits of a miscellaneous nature, including pathology, laboratory work and surgery, and twenty-two exhibits in the educational classification, making 120 exhibits in all.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards reported:

CLASS I

[Awards in Class I are made for exhibits of individual investigations, which are judged on the basis of originality and excellence of presentation.]

The gold medal to Moses Swick, Mount Sinai Hospital, New York, for original investigative work on intravenous and oral urograms demonstrating various urologic conditions by means of sodium iodolhippurate, developed by him.

The silver medal to L. F. Badger, United States Public Health Service, Washington, D. C., for original work on the differential diagnosis of Rocky Mountain spotted fever and endemic typhus, both of which occur endemically in some sections of the United States.

The bronze medal to John W. Towey, Powers, Mich., Henry C. Sweany, Chicago, and Willis H. Huron, Iron Mountain, Mich., for original investigations of a form of pneumonitis produced by the spores of a fungus (*Coniosporium corticale*) in maple bark.

Certificates of merit, Class I, were awarded to the following (alphabetically arranged):

J. L. Bollman and F. C. Mann, Mayo Clinic, Rochester, Minn., for exhibit on experimental pathology of the liver.

Ethan Flagg Butler, Chest Clinic, Arnot-Ogden Memorial Hospital, Elmira, N. Y., for exhibit illustrating physiology of respiration with particular reference to the efficiency of pulmonary ventilation and to electrobronchographic studies.

Everett S. Lain, Department of Dermatology and Radiology, Oklahoma University and Lain-Roland Clinic, Oklahoma City, for an exhibit illustrating electrogalvanic lesions of the oral cavity caused by dissimilar metallic dentures.

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

That of George C. Andrews, Frederick W. Birkman and Richard J. Kelly, Vanderbilt Clinic, Columbia University College of Physicians and Surgeons, New York, for excellence in showing recalcitrant pustular eruptions of the palms and soles not due to ringworm.

That of George A. Bennett, Department of Histology, Georgetown Medical School, Washington, D. C., for excellence in showing the effect of thorium dioxide on tuberculosis in guinea-pigs.

That of Paul L. Day, William G. Langston and K. W. Cosgrove, University of Arkansas School of Medicine, Little Rock, Ark., for excellence in demonstrating experimental cataract and other ocular changes from deficiency of vitamin C.

CLASS II

[Awards in Class II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of correlating facts and excellence of presentation.]

The gold medal to Elliott P. Joslin, George F. Baker Clinic, New England Deaconess Hospital, Boston, and Herbert H. Marks, Metropolitan Life Insurance Company, New York, for excellence of presentation of an exhibit illustrating the prevention of diabetes mellitus and certain of its complications.

The silver medal to F. P. McNamara, Finley Hospital Laboratory, Dubuque, Iowa, for excellence of presentation of an exhibit illustrating the activities of the pathologic laboratory in a hundred bed hospital.

The bronze medal to R. Plato Schwartz, Department of Surgery, Division of Orthopedics, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., for excellence of presentation of an exhibit illustrating the electrobasographic methods of recording the gait of man.

Certificates of merit, Class II, to the following (alphabetically arranged):

Charles F. McKhann and Edward C. Vogt, Children's Hospital, Boston, for excellence of presentation of an exhibit illustrating lead poisoning in children.

Francis D. Murphy and John Grill, Marquette University and Milwaukee County Hospital, Milwaukee, for excellence of presentation of an exhibit illustrating various types of nephritis.

P. F. Swindle, Marquette School of Medicine, Milwaukee, for excellence of presentation of an exhibit on angio-architecture of the eye, heart, liver, spleen and skeletal muscles.

In addition, the following exhibits are deemed worthy of honorable mention:

That of Frank J. Heck, Mayo Clinic, Rochester, Minn., for excellence of presentation in showing fundamental changes in blood cells.

That of E. S. Judd and Waltman Walters, Mayo Clinic, Rochester, Minn., for excellence in illustrating surgery of the biliary tract.

That of B. R. Kirklin, Mayo Clinic, Rochester, Minn., for excellence of cholecystographic demonstration of tumors of the gallbladder.

That of C. J. Lundy, Department of Medicine, Rush Medical College, University of Chicago, for excellence in showing the mechanism and electrocardiographic registration of the normal heart beat.

That of Charles Norris, Harrison S. Martland, A. O. Gettler, M. Helpner, B. M. Vance and A. V. St. George, Department of Forensic Medicine, New York University, University and Bellevue Hospital College, and chief medical examiner's office, New York and Essex (Newark) County, N. J., for excellence of presentation of the work of the chief medical examiner's office.

EDUCATIONAL CLASSIFICATION

A special certificate of merit is awarded to the American Social Hygiene Association for an exhibit on the modern conception of gonorrhea.

The Committee on Awards desires to commend the exhibit of the United States Pharmacopeial convention for its interesting exhibit of historical material showing past revisions of the Pharmacopeia. The committee also wishes to emphasize especially the cooperation with the American Medical Association of the government and of various national and local organizations in providing educational exhibits to show the progress of organized activities for the promotion of health and the prevention of disease.

The special exhibits arranged by the twelve sections of the Scientific Assembly have added greatly to the scope and value of the Scientific Exhibit.

The Committee on Awards invites attention to the special exhibits sponsored by the American Medical Association, namely, those on poliomyelitis, circulation of blood in the capillaries, fresh pathology and cancer, and commends particularly those physicians who have assisted in the preparation and in the presentation of these special exhibits. By their participation they are excluded from the opportunity of competing for individual awards which might have been merited by a number of them.

The committee believes that the members and Fellows of the American Medical Association owe a debt of gratitude to the Committee on Scientific Exhibit, to the Advisory Committee and to Dr. Thomas G. Hull, executive in charge, for the present exhibit. The committee cannot commend too highly the appropriate arrangement, general and special, the excellent management, the instructiveness, and the scientific as well as the practical value of the exhibit. Many physicians and investigators, often at great personal sacrifice, have submitted exhibits dealing with various aspects of all the specialties in medicine, prepared by means of modern methods and devices for the visualization of the most recent advances in medicine.

LUDVIG HEKTOEN, Chicago, Chairman.
A. F. R. ANDRESEN, Brooklyn.
H. C. BUMPUS, JR., Rochester, Minn.
THOMAS PARRAN, Albany, N. Y.
R. A. STRONG, New Orleans.

Suprarenal Cortex.—Many studies on the pathology of the suprarenal glands have lent support to the theory advanced forty years ago that the suprarenal cortex detoxifies, probably by its lipids, not only metabolic products but also bacterial toxins, and also protects the organism against bacterial invasion.—Wenner, W. F.: Effect of Extract of the Suprarenal Cortex on Maxillary Sinusitis in the Rabbit, *Arch. Otolaryng.* 17:774 (June) 1933.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a. m., Chicago daylight saving time, which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

- July 11. Food Advertising Defined.
- July 13. Does Home Canning Pay?

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

- July 15. Acne.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Clinical Meeting.—The eighth meeting of the Fort Smith Clinical Society was held at Fort Smith, June 27. In addition to clinics by Drs. Arthur F. Hoge, Jesse E. Stevenson, James W. Amis, Arless A. Blair and Pierre P. Redman, talks were given by the following physicians:

- Frederick H. Krock, Diagnosis of Some Vascular Diseases of the Extremities.
- Sidney J. Wolferrmann, Diagnostic Hints on Intestinal Obstruction.
- Walter G. Eberle, Points in Technique of Office Gynecology.
- Everett C. Moulton, Otorhinological Hazards of Swimming.
- Clarence B. Billingsley, Pyelitis of Pregnancy.
- Curtis H. Kennedy, Free Medicine.
- Ira F. Jones, Uterine Hemorrhage and Its Treatment.
- George E. Knappenberger, Kansas City, Mo., A Plea for More Exact Clinical Diagnosis of Gastro-Intestinal Diseases.

COLORADO

Gift of Books.—Dr. Francis H. McNaught, Denver, recently presented to the library of the Colorado State Medical Society several rare volumes. Included among these were "Some Notes on Midwifery" by Henry Marshall of Scotland, in the author's own handwriting, dated 1790; "A Popular Treatise on the Venereal Diseases," by Robert John Thornton, dated 1815; "Lazari Riverie Opera Medica Omnia," dated 1698, and a book of botanical specimens from Scotland more than 100 years old, collected by the McNaught family.

GEORGIA

Medical Exhibit in Public Library.—A collection of pamphlets, books, instruments, articles of equipment and manuscripts used in the early medical practice of Georgia was on display in the Savannah Public Library, it was reported, May 2. The exhibit was assembled by Dr. Victor H. Bassett, city health officer of Savannah, and includes many articles belonging to the Georgia Medical Society.

Extension Courses.—Emory University School of Medicine, the state medical association and the state board of health are cooperating in a series of summer extension courses throughout the state, the first of which opened, June 19, in Valdosta. Other series opened in Statesboro, June 26, and La Grange, July 3. Subsequent courses will be held in Athens, July 10, and Rome, July 17. Each series runs for one week. The instructors include the following physicians:

- | | |
|------------------------------------|---------------------------------|
| William L. Funkhouser, pediatrics. | Madison H. Roberts, pediatrics. |
| Frank K. Boland, surgery. | Daniel C. Elkin, surgery. |
| Cyrus W. Strickler, medicine. | Stewart R. Roberts, medicine. |
| Frederick G. Hodgson, orthopedics. | Montague L. Boyd, urology. |
| James E. Paulin, Jr., medicine. | Milus K. Bailey, urology. |

The woman's auxiliary of the state medical association sponsored a half hour program preceding each Monday session for wives of physicians.

State Society Awards.—Dr. George Lombard Kelly, professor of anatomy, University of Georgia Medical School, Augusta, was awarded the Crawford W. Long Medal for original research by the Medical Association of Georgia at its recent annual meeting in Macon. At this time it was also announced that Dr. Roy R. Kracke, associate professor of pathology and bacteriology, Emory University School of Medicine, Atlanta, will be the first physician to have his name inscribed on the Lamartine Griffin Hardman Cup. This trophy, donated to the association by former Governor Hardman, bears the following inscription:

Presented to Medical Association of Georgia by Governor Lamartine Griffin Hardman, M.D., B.S., B.A., LL.B., the first physician to be governor of Georgia in over a century, in token of his esteem for the medical profession and the department of health of the state, to be placed in the state treasury for safe-keeping and removed from time to time by the president of the association for the purpose of placing on it, in the judgment of the association, the author, date and achievement of any solution of an outstanding problem of public health or any important discovery in medicine or surgery. May 14, 1931.

Dr. Kracke's research was on diseases of the blood, particularly on agranulocytosis.

IDAHO

Society News.—At a recent meeting of the Nez Perce County Medical Society in Lewiston, speakers included Drs. Peter D. Brink, Pomeroy, on "Lymphatic Leukemia"; Christian H. Koentz, Lapwai, "Primary Tuberculous Infection," and Ralph M. Alley, Lapwai, "Types of Childhood Tuberculosis."

ILLINOIS

Society News.—The Winnebago County Medical Society held a clinic day in conjunction with the staff of St. Anthony's Hospital, Rockford, in May. Clinics were conducted by Drs. Robinson Bosworth, Rockford, on tuberculosis; Max S. Wien, Chicago, skin diseases; Philip H. Kreuscher, Chicago, dry clinic on diseases of the bones and joints, and John A. Volfer, Chicago, surgery. Drs. Theodor Lang and Harold D. Palmer, hospital pathologists, presented an exhibit of pathologic specimens. Dr. Andrew B. Rivers, Rochester, Minn., was guest speaker at the evening meeting following a banquet at the Elks Club, on "The Causes of Vomiting of Blood."

Chicago

Hospital News.—Mrs. Josie Hamburger directed in her will that a pearl necklace should be sold for not less than \$50,000 and the money used for a maternity ward in a hospital to be selected by Dr. Lester E. Frankenthal. If the choice is not made within five years, the fund will go to the Michael Reese Hospital, according to the Chicago Tribune.

Dr. Wilder Honored.—Dr. William H. Wilder was honored at a dinner by the Chicago Ophthalmological Society, June 10. Dr. Wilder is professor emeritus of ophthalmology at Rush Medical College. The eye, ear, nose and throat section of the Illinois State Medical Society held its annual meeting in honor of Dr. Wilder. In addition to personal tributes, a gift was presented to him.

Deaths Due to Trichinosis.—Ten members of a family of eleven were ill and four died recently following an outbreak of trichinosis. The father, employed as a city street sweeper, found a dead hog in an alley in the rear of a restaurant. To test its fitness for food he cooked the liver and ate it. As he suffered no ill effects, he then made sausage, some of which was eaten raw. In a week, one member of the family died. Two children became ill within forty-eight to seventy-two hours after eating the sausage. Trichina spiralis was demonstrated in portions of the hog viscera recovered by inspectors from a vacant lot, and the hospital certificates gave the cause of death as trichinosis. The board of health has not determined how the hog happened to be in the alley.

INDIANA

Personal.—Dr. and Mrs. Frank G. Jackson, Muncie, celebrated their golden wedding anniversary, May 16.—Franklin College, Franklin, conferred the honorary degree of doctor of science on Dr. Carl F. Payne, Franklin, at its annual commencement.

Park to Commemorate Physicians.—A memorial park surrounding Indianapolis City Hospital was dedicated, May 12, in honor of physicians who have gratuitously cared for patients unable to pay. Through the park is to run a trail called "Memory Lane," connecting the city hospital with the James Whitcomb Riley Hospital for Children and other hospitals of the Indiana University Medical Center. A boulder inscribed with a memorial tribute to the medical profession of Indianapolis has been placed near the city hospital. The park project.

which redeems a once desolate area, was planned and carried through by the woman's auxiliary of the Indianapolis Medical Society, with the cooperation of the city park department. The original idea of beautifying the grounds is attributed to Mrs. David Ross, widow of an Indianapolis physician.

Citizens' Committee to Coordinate Agencies.—Dr. Willis D. Gatch, dean, Indiana University School of Medicine, Indianapolis, recently appointed a citizens' committee to coordinate work of various agencies in the field of public health education as a part of the program to extend the activities of the state board of health. The selection of this committee is an extension of the general plan of reorganization of the state board of health, sponsored by Governor McNutt (*THE JOURNAL*, April 22, p. 1262). Dr. Gatch is chairman of the committee, which is composed of representatives of organizations interested in public health work. Members include the following:

George C. Cole, state superintendent of public instruction.
Dr. Joseph H. Weinstein, Terre Haute, president, Indiana State Medical Association.
A. L. Harter, D.D.S., Kokomo, president, Indiana State Dental Association.
Dr. Oscar N. Torian, department of pediatrics of the medical school.
Mrs. Glen Gifford, Tipton, active in work of American Red Cross and Public Health Nurses' Association.
Mrs. W. J. Hockett, Fort Wayne, president, Indiana Congress of Parents and Teachers.
Peter C. Reilly, trustee of the James Whitcomb Riley Hospital for Children.
Robert E. Cavanaugh, director, extension division, Indiana University.
Judge Donald F. Stiver, Goshen, of the American Legion.
Dr. John H. Hare, state director of public health.

The committee on public relations of the Indiana State Medical Association will assist the committee.

MARYLAND

Health Conference on Wheels.—The "healthmobile" of the bureau of child hygiene, state department of health, began a series of child health conferences in southern Maryland and some of the counties on the eastern shore, July 3. The conferences will be under the joint direction of the bureau of child hygiene, the division of oral hygiene and the health officer of each county to be visited.

Personal.—Dr. Hugh H. Young, Baltimore, was recently given the honorary degree of doctor of philosophy by Queen's University, Belfast, Ireland. —Dr. Anthony L. Rettaliata has been appointed full time medical health officer of Baltimore, a position recently created within the Baltimore Health Department. Dr. Rettaliata, in this new capacity, will serve as consultant to practicing physicians in the diagnosis and investigation of communicable diseases. He has been connected with the health department since 1911.

Laboratories Merged.—The consolidation of the laboratories of the Baltimore Health Department was recently announced. C. Leroy Ewing, who was assistant to the late Dr. William Royal Stokes, head of the bureau of bacteriology, is in charge. A bureau of laboratories has also been established as part of the reorganization program in the department, in accordance with a recommendation made by Dr. Joseph W. Mountin, U. S. Public Health Service, following his survey of health and hospital service in Baltimore in 1932.

MASSACHUSETTS

Personal.—Dr. Harvey Cushing, emeritus professor of surgery, Harvard University Medical School, Boston, has been made a foreign member of the Royal Society, London. —Dr. Halbert G. Stetson, Greenfield, retiring president of the Massachusetts Medical Society, was honored, May 19, on his retirement from the Franklin County Public Hospital with a special program attended by 125 friends. Dr. Arthur H. Ellis, Greenfield, presented Dr. Stetson with a set of biographic works by former Senator Albert J. Beveridge of Indiana.

Recommend Abandonment of Health Units.—Radical curtailment of the George Robert White Health Units was recently proposed by the Finance Commission of Boston, on the ground that they are new and nonessential, according to the *New England Journal of Medicine*. This recommendation was contained in a memorandum suggesting a reduction of 10 per cent, or \$75,000, in the expenditures of the Boston Health Department. In referring to the health units, the memorandum says:

Valuable as they may be, the City could continue to function without the White Health Units, without the dental work, without the tuberculosis clinics, without the baby clinics and without any of the lesser functions of the Health Department. They represent services to the citizens of Boston; not essential services of the City as a governmental unit.

The Boston Health League, in a statement sent to the commission, was of the belief that the health units and their major services were essential services, conducted economically. The health units were established through the George Robert White

Fund and presented to the city as educational institutions for the training of the public in health conservation. The first unit was established in 1915, and the seventh, the last, was dedicated, February 24 (*THE JOURNAL*, March 25, p. 977). The commission further recommended a reorganization of the health department for reasons of economy.

MICHIGAN

Children's Fund Suspends Contributions.—The Children's Fund of Michigan has suspended its contributions to the Grand Rapids Child Guidance Clinic because the curtailment of funds was found necessary. Dr. Milton E. Kirkpatrick, director of the clinic since it opened in May, 1931, was to depart, May 1, to accept a position as psychiatrist in the juvenile court at Cleveland.

Cancer Bureau Established.—Transfer of the cancer division of the Detroit Department of Health to the headquarters of the Wayne County Medical Society marks the establishment of a cancer bureau, sponsored jointly by the department of health and the society. With the stimulation of interest in cancer among local members of the medical profession as an objective, the removal is considered as an initial step to concentrate important activities of the society under one roof.

Fifty Years in Practice.—Drs. Walter E. Ward, Owosso, and Jacob S. Shoemaker, New Lathrop, were honored by the Shiawassee County Medical Society with a dinner, recently, in celebration of their completion of fifty years in the practice of medicine. Both physicians graduated from the University of Michigan with the class of 1883. Honorary memberships were conferred on Drs. Ward and Shoemaker, and each was presented with an electric clock. Speakers included Drs. George L. LeFevre, Muskegon, president-elect of the Michigan State Medical Society, and Dr. James D. Bruce, Ann Arbor, a former associate of Dr. Shoemaker. Three former presidents of the state society, Drs. Arthur M. Hume, Owosso, Herbert Randall and Carl F. Moll, Flint, were present.

MINNESOTA

Immunization Campaign.—The Minneapolis health department and the Hennepin County Medical Society are cooperating in an immunization campaign against smallpox and diphtheria. Members of the society are being reimbursed by the city for vaccinations. Cards are provided for purposes of record, free and pay vaccinations being kept separately. Dr. Chester A. Stewart, Minneapolis, president-elect of the medical society, is chairman of the committee on vaccination.

Medal to Dr. Hanson.—A gold medal was awarded to Dr. Adolph M. Hanson, Faribault, by the Minnesota State Medical Association at its recent annual session in Rochester, in recognition of his isolation of the parathyroid hormone. Dr. William J. Mayo, Rochester, presented the medal. In December, 1932, the U. S. Patent Office confirmed Dr. Hanson's claim to the discovery. Dr. Hanson has made the Smithsonian Institution, Washington, D. C., the benefactor of all royalties, for the furtherance of scientific research. Dr. Hanson graduated from Northwestern University Medical School, Chicago, in 1911 and is now engaged in private practice. A gold medal was also awarded to Dr. Ralph V. Ellis and Carl O. Rosendahl, Ph.D., of the University of Minnesota by the Southern Minnesota Medical Society, for their exhibit on causes of hay fever in Minnesota.

MONTANA

Society News.—A special meeting at the tumor clinic of the Murray Hospital, Butte, was held, May 25, with forty physicians from the southwestern part of Montana in attendance; the program consisted of the presentation of cases for diagnosis and results of treatment.

NEW YORK

Personal.—Dr. Christopher G. Parnall, medical director of the Rochester General Hospital, has been appointed commissioner of public welfare, according to newspaper reports. He is a former president of the American Hospital Association. Dr. Harry D. Clough, for several years assistant medical director of the hospital, has been named medical director to succeed Dr. Parnall.

Resolution About Technicians and Nurses as Anesthetists.—At the recent annual meeting of the Medical Society of the State of New York, a resolution was adopted urging that the giving of anesthetics by nurses and lay technicians be discontinued. Declaring that for many years the medical practice act of the state had been interpreted to mean that administering of anesthetics by any persons except licensed physicians

and dentists was illegal, the resolution pointed out that during the past ten years lay technicians have usurped the duties and rights of licensed physicians in this field. The spirit of the law is evaded, it was said, by the technical assumption of responsibility by the surgeon, but in fact the surgeon rarely selects or inquires into the anesthetist's qualifications and does not usually see the patient during the induction of anesthesia. This growing custom is depriving interns and residents of opportunity for instruction in this branch of medicine, yet they are the practitioners of the future who will be called on to assume responsibility for administration of anesthesia. The resolution urged the society to insist on a strict interpretation of the medical practice act and, if the attorney general was of the opinion that the present act does not adequately cover the situation, to institute measures to obtain proper legislation to limit administration of anesthesia to licensed physicians and dentists.

New York City

Personal.—Dr. Florence Rena Sabin of the staff of Rockefeller Institute for Medical Research received the honorary degree of doctor of science at the recent commencement of New York University. —Dr. William Ainslee Goodall was the guest of honor at a banquet, May 6, at the Hotel Astor, celebrating his fiftieth anniversary in the practice of medicine. Dr. Frederick L. Flynn presided and speakers included Drs. Charles Gordon Heyd and John G. William Greeff.

NORTH CAROLINA

Society News.—Dr. Paul H. Ringer, Asheville, addressed the Buncombe County Medical Society, June 5, on hypoglycemia. —Dr. Henry L. Sloan addressed the Mecklenburg County Medical Society, Charlotte, June 6, on 100 consecutive operations for cataract. —Dr. Oliver W. Hill, Knoxville, Tenn., was guest speaker at a meeting of the Tenth District Medical Society at Waynesville, May 17, on "Blood Dyscrasia in Children."

Personal.—Dr. William de Berniere MacNider, Kenan professor of pharmacology, University of North Carolina School of Medicine, Chapel Hill, was awarded the honorary degree of doctor of science at the commencement exercises of the Medical College of Virginia, Richmond, May 30. —Dr. John Peter Munroe, Charlotte, received an honorary degree from Duke University at its summer commencement, and Dr. Thurman D. Kitchin, Wake Forest, was similarly honored by the University of North Carolina.

New Director of State Laboratory.—Dr. John H. Hamilton, director of the division of county health work and epidemiology of the North Carolina State Board of Health since 1931, has been appointed director of the laboratory to succeed the late Dr. Clarence A. Shore. Dr. Hamilton was graduated from Harvard University Medical School in 1916, after which he served as a bacteriologist with the New York State Department of Health and the Iowa State Board of Health and later was on the staff of the Rockefeller Foundation. In 1920 he was made health officer of New Hanover County and the city of Wilmington, where he served until his appointment to the state board staff in 1931. Since January, 1932, he has also been in charge of vital statistics.

OHIO

Society News.—Dr. John A. Caldwell was recently elected president of the Cincinnati Academy of Medicine. —Dr. Henry Kennon Dunham, Cincinnati, addressed the Clinton County Medical Society, Wilmington, June 6, on pulmonary tuberculosis. —The Clark County Medical Society held a clinical meeting at Springfield City Hospital, June 14, followed by the annual outing at Springfield Country Club. —Speakers on the scientific program of the eighth district meeting of the Ohio State Medical Association at Rocky Glen Sanatorium, McConnelsville, June 22, were Drs. Russel G. Means, on "Sinusitis in Relation to Chronic Bronchitis"; Eugene William Masters, "Management of Infections Complicating Diabetes"; Fred Fletcher, "Gynecologic Problems," and Sylvester J. Goodman, "Postpartum Hemorrhage." All speakers were from Columbus. —Drs. William B. Morrison and Robert L. Barnes, Columbus, addressed the Washington County Medical Society, Marietta, June 14, on "Modern Treatment of Benign and Malignant Lesions of the Stomach and Duodenum" and "Recent Advances in Treatment of Arthritis." —Dr. Roy W. Scott, Cleveland, addressed the Montgomery County Medical Society, June 2, on "Management of the Patient with Cardiovascular Disease." —Drs. Edmund C. Mohr and Murray E. Goodrich, Toledo, presented an illustrated lecture on "Diagnosis of Small Lesions of the Uterus and Tubes" before the Williams

County Medical Society, Bryan, in April, and Dr. Stanley D. Giffen, Toledo, spoke on "Vomiting in Infants and Small Children." Physicians of four surrounding counties were guests.

PENNSYLVANIA

Hospital Burned.—Fire caused about \$500,000 damage to the Robert Packer Hospital, Sayre, May 3. The fire is believed to have started from electric wiring in the basement. Two hundred and twenty-three patients were safely removed and within forty-eight hours the hospital was said to be functioning at 50 per cent of its normal capacity. Patients seriously ill were taken to the Tioga General Hospital, Waverly, N. Y., and others were cared for in adjacent buildings.

New Hospital Dedicated at Darby.—Ceremonies dedicating the new Thomas M. and May F. Fitzgerald Mercy Hospital at Darby were held, May 21, with Cardinal Dougherty officiating. The new hospital, eleven stories high, was built at a cost of \$1,250,000 from a fund left by the late Thomas M. Fitzgerald of Landsdowne. Dr. Cornelius T. McCarthy is chairman of the board of trustees which planned the hospital with Mrs. Fitzgerald. It will be managed through the Catholic Diocese of Philadelphia.

Philadelphia

Illegal Practitioners Convicted.—Michael Fiorillo, a naturopath, and Vincenzo Naselli were recently convicted of practicing medicine without a license. Both were placed on probation for one year and were ordered to pay the cost of the prosecution.

Personal.—Charles S. Pitcher resigned as superintendent of Presbyterian Hospital, Philadelphia, June 1. Mr. Pitcher is president-elect of the Protestant Hospital Association. —Dr. McCluney Radcliffe received the honorary degree of doctor of science at the annual commencement, June 9, of Lafayette College, his alma mater.

Jefferson Alumni Meet.—Two days of clinics constituted the program of the annual meeting of the Alumni Association of Jefferson Medical College, May 31-June 1. Among speakers were Drs. P. Brooke Bland, on intracranial injuries of the newborn, Thomas McCrae and Louis H. Clerf, on carcinoma of the lung, and George R. Bancroft, Ph.D., on treatment of cyanide or carbon monoxide poisoning by methylene blue. Dr. Thomas A. Shallow was elected president of the organization.

Preventorium Treatment.—A three year demonstration of the value of preventorium care of children with latent tuberculous infection was begun by the Philadelphia Health Council and Tuberculosis Committee, July 1, when twenty-five children were to be sent to River Crest Preventorium, Mont Clair. The council has requested a score of official and unofficial chest clinics to register all children showing signs of latent tuberculosis. It is planned to send 100 children each year to the preventorium, where the council has assumed maintenance of twenty-five beds. They will remain until they have acquired better health, which it is believed will require about three months. The children are being selected as a result of roentgen examinations in the public schools made through the joint efforts of the board of education, the Henry Phipps Institute and the health council.

TENNESSEE

District Health Departments.—Provision has been made for the formation of district health departments in counties of less than 20,000 population through the combination of two or more contiguous counties and the establishment of a district board of health through the passage of an act in the recent legislature. According to *Health Briefs*, this will provide for fundamental improvement of local health service in the smaller counties of the state and make possible grouping of counties to form a population unit of sufficient size to support an effective organization.

Sectional Society Meetings.—Dr. Charles F. Anderson, Nashville, was elected president of the Middle Tennessee Medical Association at its annual meeting in Woodbury in May. Among others, Dr. Lonnie D. Allen, Smithville, presented a paper on "Medical Practice and Distribution of Doctors in Tennessee"; Dr. Jefferson C. Pennington, Nashville, on "Surgery of Transurethral Resection" and Dr. William T. Robison, Murfreesboro, "Avertin Anesthesia." —Dr. George R. McSwain, Paris, was elected secretary of the West Tennessee Medical and Surgical Association at the annual meeting in Shiloh Park, May 25-26, succeeding his father, the late Dr. Isaac A. McSwain, who served forty years. Among speakers were Drs. William D. Haggard and Carl R. Crutchfield, Nashville.

on "Early Diagnosis of Cancer of the Colon and Rectum," and John Preston Kennedy, Greenwood, Miss., "Radium Therapy in the Treatment of Uterine Hemorrhage of Benign Origin."—Dr. William M. Brown, Livingston, was elected president of the Upper Cumberland Medical Society at its thirty-ninth annual meeting in Red Boiling Springs, June 6-7. Among others, Dr. Louis W. Frank, Louisville, Ky., delivered an address on "Cancer of the Cervix Uteri"; Drs. Oliver W. Hill, Knoxville, on "Blood Dyscrasias in Infants and Young Children"; William D. Haggard, Nashville, "Diagnosis and Surgical Treatment of Cancer of the Rectum"; James S. Campbell, Lebanon, "Gangrene," and Beverly Douglas, Nashville, "Radical Versus Conservative Treatment of Varicose Ulcers of the Leg."

WASHINGTON

Annual Graduate Course.—The University of Washington will present its seventeenth annual course of graduate lectures and clinics for physicians, July 17-21. Lecturers will be Dr. Louis A. Buie, Rochester, Minn., on proctologic subjects; C. Frederic Fluhmann, San Francisco, obstetrics and gynecology; Thomas B. Fletcher, Baltimore, medicine and therapeutics, and Arthur C. Strachauer, Minneapolis, surgery. Six lectures and two clinics will be presented daily, with lectures on nonmedical topics each evening following informal dinners. The fee will be \$10. Since the University of Washington has no medical school, the institution takes this method to bring to the medical profession of the Northwest the latest developments in the different branches of medical science.

Society News.—Dr. Alexander H. Peacock, Seattle, president of the Washington State Medical Association, addressed the King County Medical Society, June 5, on "What the State Medical Association Is Doing for the Community."—Dr. Albert L. Mathieu, Portland, Ore., addressed the Chelan County Medical Society, Wenatchee, in May, on diagnosis in the lower part of the abdomen.—Dr. John N. Alley addressed the Pierce County Medical Society, Tacoma, May 10, on treatment of tuberculosis.—Drs. James Tate Mason and Louis H. Edmunds, Seattle, addressed the Skagit County Medical Society at a recent meeting at Northern State Hospital, Sedro Woolley, on "Problems of Cholecystitis" and "Fractures of the Lower Extremities" respectively. Dr. Pius A. Rohrer, Seattle, demonstrated methods of transurethral prostatic operations.

GENERAL

Society Changes Name.—At the recent annual meeting of the American Association for the Study of the Feeble-Minded, its name was changed to the American Association on Mental Deficiency. Officers elected are Drs. Ransom A. Greene, Waverley, Mass., president; Mary M. Wolfe, Laurelton, Pa., vice president, and Groves Blake Smith, Godfrey, Ill., secretary. The next annual meeting will be held in New York.

Activities of Food Administration.—Seizure of 140 consignments of foods and drugs during May was reported by the federal Food and Drug Administration. Seizures included: adulterated and misbranded livestock remedies; aspirin tablets; proprietary remedies falsely and fraudulently labeled as having remedial values in such diseases as pyorrhea, goiter, rheumatism, acidosis, liver disorders, diabetes, hay fever and deficiency disease; apples carrying residues of poisonous sprays; misbranded butter, oysters and other commodities. Prosecution was recommended in cases involving forty stocks of food, drugs and insecticides. Notification was received from federal courts of nineteen criminal prosecutions during the month, resulting in fines varying from \$5 to \$600.

Dana Medal Awarded.—Dr. William H. Luedde, director of the department of ophthalmology, St. Louis University School of Medicine, was awarded the Leslie Dana Gold Medal, June 19, by the Missouri Association for the Blind in cooperation with the National Society for the Prevention of Blindness. The award is made annually. Lewis H. Carris, director of the national society, said in making the presentation that Dr. Luedde, as director of the prevention of blindness department of the Missouri Commission for the Blind from 1913 to 1926, had been active in developing the movement for saving sight in the state. He is said to have been instrumental in the enactment of legislation for prevention of ophthalmia neonatorum in the state. He has also been director of the prevention of blindness department of the Missouri Association for the Blind.

Reduced Appropriation for Spotted Fever Vaccine.—A protest from Gov. Leslie A. Miller of Wyoming against reduction of appropriations for research by the U. S. Public Health Service on Rocky Mountain spotted fever was presented to the United States Senate, June 14. Senator John B. Kendrick

of Wyoming read to the Senate a letter from Surg. Gen. Hugh S. Cumming in which it was stated that the vaccine for Rocky Mountain spotted fever is already so limited that it has been necessary to deny it to members of the Civilian Conservation Corps and the troops of the U. S. Army in order to reserve it for civilians in areas where the disease is most prevalent and severe. The appropriation for the next fiscal year is \$49,000, compared with a previous \$83,000. No action was taken by Congress to increase the appropriation and future expenditures may depend on recommendation by the director of the budget. it was stated.

Society News.—Dr. Lena K. Sadler, Chicago, was named president-elect of the Medical Women's National Association at the annual meeting in Milwaukee, June 12, and Dr. Mary O'Malley, Washington, D. C., was installed as president. Drs. Mary Louise Small, Baltimore, Eleanor Cushing-Lippitt, Milwaukee, and Louise W. Beamis-Hood, Buffalo, were elected vice presidents, and Dr. Elizabeth A. Kittredge, Washington, D. C., secretary.—Dr. Louis Faugeres Bishop, New York, was elected president of the American Therapeutic Society at its annual meeting in Milwaukee, June 10. Drs. Alpheus F. Jennings, Detroit, Richard J. Behan, Pittsburgh, and Truman G. Schnabel, Philadelphia, were elected vice presidents, and Dr. Oscar B. Hunter, Washington, D. C., secretary, reelected. The society conferred on Dr. Bernard Fantus, Chicago, the honorary degree of doctor of therapeutics; this is said to be the first time the honor has been given to an American.—Dr. Frank J. Broschart, Gaithersburg, Md., was elected president of the Virginia, Maryland and District of Columbia Medical Society at its meeting in Alexandria, Va., May 24: Dr. James A. Gannon, Washington, D. C., is the recording secretary.

Chattahoochee Valley Medical Association.—The thirty-third annual session of the Chattahoochee Valley Medical and Surgical Association will be held at Radium Springs, Albany, Ga., July 11-12, with headquarters at the Casino Building, under the presidency of Dr. Seale Harris, Birmingham, Ala. Physicians included on the program are:

Herbert B. Dowling, Mobile, Ala., Modification of Aschheim-Zondek Test for Early Pregnancy.
William Howard Hailey, Atlanta, Hypertrichosis.
Louie M. Limbaugh, Jacksonville, Fla., Artificial Pneumothorax in Pulmonary Tuberculosis.
Willis P. Jordan, Columbus, Ga., Sedimentation in Urological Conditions.
Adolph E. Drexel, Palatka, Fla., A Urinary Precipitant in the Therapeutics of Asthma.
John C. Patterson, Cuhbert, Ga., Diverticulosis of the Sigmoid.
Nicholas A. Balizell, Marianna, Fla., Appendicitis—Its Management and Treatment with a Plea Toward Reasonable Conservatism in Abscess Cases and Those Involving a Local Peritonitis.
Claude C. McLean, Birmingham, Age Incidence of Climatic Variations in the Manifestations of So-Called Rheumatic Fever in Children.
Henry Mason Smith, Tampa, Role of Alcohol in Therapeutics—in Accidents and in Producing Pathological Drunkenness.
Thomas Harrold, Jr., Macon, Ga., Surgery and Radiation in the Treatment of Cancer of the Mouth.
Leroy H. Oeljen, Leesburg, Fla., Surgical Treatment of Cleft Palate and Harelip.
James F. Alison, Selma, Ala., Carbon Dioxide—Oxygen Inhalations in the Treatment of Pneumonia.

Leprosy Research in the Philippines.—Investigations under the auspices of the Leonard Wood Memorial Foundation for the Eradication of Leprosy will begin during this year with the initiation of research in the Philippine leper colonies by three members of the Advisory Committee of Research. Dr. James A. Doull, professor of hygiene and public health, Western Reserve University School of Medicine, Cleveland, left, March 25, for the Philippines, and Malcolm H. Soule, D.Sc., professor of bacteriology, University of Michigan Medical School, Ann Arbor, and Dr. Frederick P. Gay, professor of bacteriology, Columbia University College of Physicians and Surgeons, and chairman of the committee, are expected to follow shortly. Named in honor of the late Leonard Wood, physician, army officer and governor-general of the Philippines, the memorial has an endowment of \$2,000,000, subscribed through the pledges of 50,000 persons; \$400,000 was expended for a new leprosarium in Cebu and for construction at Culion. These buildings, comprising laboratories, research wards, housing facilities for nurses and scientific personnel, and a cabin cruiser to facilitate transportation, have been completed and handed over to the Philippine government. A medical board, also composed of volunteers, of which Dr. William H. Welch, Baltimore, is chairman, advises on the expenditure of funds. Dr. Herbert W. Wade is medical director of research at Culion. With the aid of the memorial, a journal of leprosy is about to be published by the International Leprosy Association. It was also through the memorial's support that the first international conference on leprosy took place in Manila in 1931.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 10, 1933.

Edinburgh Students Condemn the Medical Curriculum

In view of the recent criticism of the medical curriculum, the students' union of Edinburgh University held an important debate on the subject. Dr. Chalmers Watson, senior physician to the Edinburgh Royal Infirmary, who had been invited to address the meeting, said that in recent discussions there was practical unanimity as to the following defects in the curriculum: (1) excessive time and attention devoted to unnecessary detail in the preliminary subjects—*anatomy, physiology and pathology*—and failure to correlate these subjects adequately with the clinical work; (2) defective appreciation of limitations to the value of teaching by specialists in its relation to the work of the physician; (3) lack of attention to many subjects of great practical importance in preventive medicine. In Edinburgh, 900 hours of the curriculum was devoted to anatomy, whereas the hours devoted to medicine—essentially the life work of the physician—numbered only 450. In Yale, Harvard and other American universities the figures were far different, being 260 and 1,100 hours, respectively. By change of outlook and by teaching the anatomy of the living, as opposed to the minute anatomy of the dead, a saving of 500 hours could be effected with enormous advantage to the student. This changed outlook would bring about other notable changes—the beginning of clinical work in the first, as opposed to the third, year; an increase in the time for physiology, which should be taught much more applied than at present; more attention to practical surgery in the outpatient departments, at the expense of time wasted in the operating theater; special subjects to be taught from the point of view of the general practitioner rather than of the specialist; more tutorial as opposed to mass teaching, and a period of three terms at the end of the curriculum in which the student should be engaged in clinical work, with no further theoretical examinations confronting him. These changes would not involve any extension of the present five-year curriculum.

In the discussion, G. H. Colt, professor of surgery, Aberdeen University, said that one of the things that were demoralizing the medical profession was the number of students who were selected for the medical career by their parents for the social position it would give them. He was prepared to teach in a fortnight all the anatomy any physician was likely to require. Mr. Godfrey of the department of anatomy, Edinburgh University, objected to the belittling of anatomy as a subject for study. The teachers were doing their best to correlate it with surgery and medicine. Another speaker said that on the teaching staff there were too many specialists without practical experience of general practice, who consequently did not know what the student required. After an animated discussion the following resolution was carried by an overwhelming majority: "That this house places on record its opinion that the present system of medical education is unsatisfactory. In its opinion important changes in the curriculum are essential, whereby more facilities for instruction in practical medicine would be available and more assistance given in the principles and practice of preventive medicine. The time required for this additional teaching can be obtained by a judicious modification in the teaching of the earlier scientific subjects, with some revision of the time devoted to the teaching in the special departments of medicine and surgery."

Changes in the Character of Scarlet Fever

The character of scarlet fever has undergone changes which are a complete mystery. In the seventeenth century Sydenham, who has been described as "the English Hippocrates," because

of his eminence as a clinical observer, and who was a great authority on fevers, regarded scarlet fever as trivial disease and even in the early days of the nineteenth century it was so considered. Then it took on a much more dangerous form. From 1890 to 1900 the standardized death rate was 133 per million. Then an extraordinary decline in virulence, for which no explanation can be given, began and the death rate fell to 18 per million in 1929. In 1851 the deaths registered from scarlet fever in England and Wales totaled 13,634; in 1931, when the population was much greater, they totaled only 540. These facts are shown in a report issued by the Medical Research Council entitled "Epidemiological Study of Scarlet Fever," by Miss Hilda M. Woods of the London School of Hygiene and Tropical Medicine. This change of character cannot be attributed to any improvement in hygienic conditions, for it is not accompanied by any corresponding decline in incidence which plausibly might be attributed to these. The mildness of the disease in Sydenham's time also negatives such an explanation. No evidence exists that hospital isolation has played any part in reducing the mortality or that such factors as overcrowding or poor social condition are of any importance. All that can be said is that, like some other diseases, such as influenza, scarlet fever may undergo periodic variation in severity. There is no guarantee that a severe form may not again be reverted to, though justification exists for believing that no sudden change is likely to occur. Exact records as to incidence do not exist before 1911. In that year the attack rate was 2.9 per thousand of population; in 1930 it was 2.76. The death rate has been reduced equally for children and for adults. The downward trend of severity has been fairly steady except for the war years.

The Use of Gas in Preserving Fruit

In 1917 the food investigation board set a team of young men to work in the Cambridge University laboratories on the use of gas in the storage of fruit. The idea was that the control of the constituents of the atmosphere in which fruit is kept might prove as effective as the control of temperature in cold storage and so provide an alternative. The results of atmospheric control have now been published. The apple was chosen as a convenient subject for experiment. It was soon found that apples keep much better in an atmosphere rich in carbon dioxide and poor in oxygen than similar fruit kept in air, but at ordinary temperatures an excess of carbon dioxide injured the fruit, causing patches known as brownheart. The next step was to find the right proportion of the two gases. This is not easy, for while apples themselves are relied on to give off the carbon dioxide required for their own preservation, the more they give off the more quickly is the oxygen in the storage chamber spent and the balance between the two gases upset. To counteract the exhaustion of the oxygen in the atmosphere, controlled ventilation with fresh air was introduced, and another important discovery was made. Up to this stage there had been no control of the temperatures of the atmosphere of the storage chambers, but various developments, of which the self heating of the stored apples was one, led to another major discovery—that the control of the temperature was as essential as the control of the gaseous composition of the atmosphere. It was ultimately found that for an apple very susceptible to injury from low temperature (Bramley's seedling) a mixture of 10 per cent of oxygen and 10 per cent of carbon dioxide at 40 F. gave better results than ordinary cold storage. An immediate result was the construction of stores for the keeping of this apple, and a practical result is that ample supplies are now available at the beginning of May. Though gas storage is only in its infancy, market opinion favors it over cold storage as regards color, flavor and firmness. Moreover, it enables apples to remain fresh during the ordinary process of distribution and marketing.

The application of the principle to other fruits as well as to fish and meat is doubtless only a question of time. It remains

for engineers to work out the practical application of this research work.

Four Hundred and Ninety-Seven Foreign Bodies in the Stomach

The practice of swallowing all sorts of articles by some lunatics is well known, but the discovery of 497 articles, weighing $3\frac{1}{2}$ pounds, in a man's stomach constitutes a record. An inquest was held at the County Mental Hospital, Upton, near Chester, on the body of a farmer, aged 28, who died in hospital following an operation. In his stomach were found 497 articles, which included 200 nails from half an inch to $4\frac{1}{2}$ inches long, 36 staples, 43 phonograph needles, 6 teaspoons, 3 table forks, 7 coins, 6 brace buckles, 3 door keys, 3 penknives, 3 S-shaped meat hooks, 10 safety-pins, 4 sewing needles, 6 ordinary pins, 13 pieces of glass or earthenware and 9 screws. The medical superintendent said that the man had a delusion that his stomach was too smooth. Death was due to ulceration of the stomach and hemorrhage.

The Treatment of Tuberculosis

At the congress of the Royal Institute of Public Health, Sir P. Varrier Jones, who has made the most important recent advance in the treatment of tuberculosis—the village settlement—urged that no treatment would be effective until provision was made not only for the tuberculous patient but for the welfare of his family also. He criticized the system by which "patched-up" patients returning from the sanatorium were sent home to die in the midst of undernourished and poorly housed families whose resistance to disease was low. The sanatorium system was not working because its starting point was that of the well-to-do. It had been forgotten that for the average man three, six or nine months in a sanatorium may mean permanent dislocation of a career. The village settlement was an attempt to compensate for that dislocation. It keeps a man away from the surroundings in which he contracted his disease and offers an opportunity of a new career and of family life in circumstances that do not constitute a danger to wife and children. He urged the value of "the family unit solution, which the almost self-supporting village settlement provides." He also pleaded for more research. The complex of biochemical factors that revealed itself as toxemia really determined the course of the disease. The only factors that really mattered were the action and interaction of the tissue fluids and internal secretions, since it was these which determined the degree of reaction to the tuberculous toxemia. It was already known that automatic healing could occur, and if the reason for its occurrence could be discovered, a way might be found to make an end of tuberculosis.

Balancing the Budget by Increasing the Saloons

The draft of the national budget as presented to parliament contains an item that has aroused the indignation of all hygienists. Some means must be found to balance the national budget, which shows a deficit of 3,000,000,000 francs (\$144,000,000). The members of the chamber of deputies have not the courage to reduce expenses by lowering the salaries of countless clerks and petty officials; by the reduction of pensions, which have reached an enormous height; by eliminating the waste represented by social insurance—all of them expenditures that were launched during the period of prosperity and from which the beneficiaries will not permit reductions. It appears that the sole interest of the deputy is the promotion of his reelection, even though that is accomplished at the expense of the general welfare. Already the appropriation granted to the ministry of public health has been greatly reduced, and its revenue will be further diminished by the decrease in the

share of the profits paid to the government for racetrack and gambling privileges, as a result of the economic crisis. But a more serious menace threatens the public health. In order to provide new revenues, the government has suggested measures designed to increase the annual income without raising too strong protests. One measure proposed is the licensing of 2,000 new places for the dispensing of alcoholic beverages. The number of such places in France is already large. To this and to the scandalous privilege enjoyed by grape growers of retaining every year, for their own use and without payment of dues, "twenty liters of alcohol," is due the maintenance of alcoholism in France in excess of any other European nation. Sweden and Switzerland, which formerly headed the nations consuming alcoholic beverages, have rapidly dropped below France by simply restricting the number of cabarets. This was brought about in Sweden by the introduction of the famous Gothenburg system. It has never been possible to effect the adoption of the system in France by reason of the tyrannical influence on the members of parliament of the powerful syndicates controlling the sale of alcoholic beverages. In some villages in the North one finds a place for dispensing alcoholic beverages for every five houses. In the new budget, which provides for 2,000 new dispensing places, the government plans to increase its revenue by about 2,000,000 francs (about \$100,000). But the hygienists say that the increase in places dispensing alcohol will increase the number of persons affected with diseases of the liver, kidneys and brain, and also the number of degenerate and tuberculous children for whom the state would have to care in the hospitals, asylums and sanatoriums, at an expense twenty times greater than the additional income the government hopes to secure. In the senate, Justin Godart, formerly minister of public health, vigorously protested against the proposal, presenting arguments in the interest of the public health. He showed that all nations are fighting alcoholism and that France, the country most affected by this type of degeneration, is taking action which will make present conditions worse. The senate and the chamber of deputies nevertheless adopted the plan. The only concession that Mr. Godart was able to secure was that the new dispensing places should be established only in small communes that have no dispensing places. The minister of health lent support to the measure by endeavoring to make it appear that the new drinking places would be a praiseworthy innovation. The protests of the hygienists and of the *Fédération des syndicats médicaux du département de la Seine* could be presented only in the medical journals and in the large reviews. The daily press, being more or less in league with the dealers, owing to important advertising contracts, did not take notice of the event.

The Grand Prix of Monaco

The *grand prix* of 10,000 francs (\$480), established by a legacy of the Prince of Monaco, to be awarded every two years by the Academy of Medicine to a scientist whose career has been characterized by medical discoveries, has been bestowed on Dr. Héricourt, who was the collaborator of Charles Richet in the introduction of serotherapy. Born in 1850, he became at first an army physician; then, from 1885 on, he devoted himself to pure science and became head of the laboratory of the department of physiology at the *Faculté de médecine de Paris*. He sought no further distinction in the scientific hierarchy. After the introduction of serotherapy, he sought to apply it to the treatment of tuberculosis and cancer but without results. He has published several books: *les Frontières de la maladie*, *l'Hygiène moderne*, *les Maladies des sociétés*. He gave up scientific research some time ago. The Academy of Medicine is tending more to award its richest prizes to old men, apparently with the desire of comforting them during the short time that remains in which to enjoy the rewards of tardy good fortune.

The Number of Panel Physicians in Germany

In a recent letter (THE JOURNAL, May 13, 1933, p. 1554), a report was given on the number of physicians in Germany. That report can now be supplemented by information on the *Kassenärzte*, or panel physicians, as recently furnished by Dr. Hadrich in the *Ärztliche Mitteilungen*. The two reports supplement each other and reveal no inconsistencies. This new information could be given out owing to the fact that the Reichs-arztregister is now far enough along so that the first results of the census are now available.

Percentage of Panel Physicians

| | Total Number | Panel Physicians |
|----------------------------|-----------------|---------------------|
| Physicians in general..... | 52,000 | 32,152 |
| Specialists* | 15,828 | 10,079 |
| Women physicians | 3,400 | 1,475 |

* The term "specialist" was defined in the THE JOURNAL, Sept. 17, 1932, page 1007.

It is evident that about 60 per cent of the German physicians are engaged in panel practice, whereas approximately 20,000 are not so engaged. About two thirds of the specialists are, at the same time, panel physicians. Of the women physicians, not quite half are in the service of the health insurance societies. In certain regions and provinces in which the number of physicians is small, these average figures are relatively much higher, and in some sections it may happen that nearly all physicians are admitted to panel practice. The distribution of the specialists among the various branches of medicine is not the same among the panel physicians as among the physicians in general, concerning which latter distribution statistics were given in a former letter. Among the panel physicians, the dermatologists present the highest proportion (15.8 per cent). The laryngologists, rhinologists and otologists come next, with 12.9 per cent. The gynecologists are represented by 12.8 per cent, the internists by 12.2 per cent, and the ophthalmologists by 11.7 per cent. Next in order are the pediatricians with 7.8 per cent and the surgeons with 7.0 per cent, to which may be added the specialists for surgery plus diseases of women (4.9 per cent), and the specialists for surgery plus orthopedics (1.6 per cent). The figures for the psychiatrists are 5.6 per cent; diseases of the stomach, 1.7 per cent; diseases of the lungs, 1.6 per cent; orthopedics, 1.4 per cent; roentgenology, 1.2 per cent; urology, 1.2 per cent; diseases of the mouth and jaws, 0.4 per cent, and, finally, disorders affecting the legs, 0.2 per cent.

Of the 3,400 physicians, 2,521 are in charge of a regular practice. Of that number, 1,475 are engaged in panel practice, and 66.6 per cent in general practice. However, the new regulations concerning admission to panel practice will change these percentages to a great extent, so that, after July 1, a new computation will be needed.

Physical Education in Higher Schools of Learning

The Bavarian ministry of public instruction has issued a decree calling attention to the fact that especial importance should be attached to the physical education of the youth. Students in higher institutions of learning must be required to set a good example in this regard. Henceforth, all men students entering on their first semester studies during the summer semester will be required to take part in physical training, with especial emphasis on the art of self-defense, for at least one period weekly during the semester. Students claiming exemption must secure a certificate from the medical director of sport activities, setting forth the reasons for exemption. The execution of this decree rests on the academic institutes for physical training, in cooperation with the student associations.

The executive committee of the league of associations of German medical students has approved in principle the application of the "voluntary work service" for medical students, both men and women. As a precondition, it demands, however, that the time spent in the voluntary work service be applied in full to the three-year period of aid service, which, according to a recent ruling, must precede admission to panel practice, and that, at the conclusion of the voluntary work service, every future medical student be required to serve for several weeks as a nurse.

The Final Decision in the Lübeck Disaster

In several previous letters (THE JOURNAL, Jan. 30, 1932, p. 414; Feb. 13, 1932, p. 566; April 9, 1932, p. 1316; April 16, 1932, p. 1394), information has been given on the measures adopted for the investigation of the multiple deaths of infants in Lübeck, caused by the administration of a virulent culture of tubercle bacilli, and concerning the decisions of the courts. A final decision has now been rendered. The federal supreme court, the court of final jurisdiction, denied, June 1, any further revision of the case. In his plea for revision, Professor Deycke set forth that in reality no tort had been proved. It had been impossible to establish by what concrete process the poisoning of the BCG cultures occurred. The narration of the occurrences sufficed, however, to show that the danger of a confusion of vaccines lay near at hand. The evidence revealed that Professor Deycke entrusted the treatment with the BCG cultures to a nurse who had not had the proper preliminary training for such work, and that thereby the safety of the laboratory was endangered. Furthermore, the behavior of Deycke that established a causal relation with the disaster and his guilt lay in the submission of the vaccine contaminated by the virulent stain. Obermedizinalrat Dr. Altstaedt, a codefendant, had based his plea for a revision on the fact that the judge in the Lübeck trial had had an attack of nervous prostration after the trial, which was followed by his death. To this the supreme court replied that a mental disease had not been proved and appeared highly improbable.

Misleading Food Propaganda

Some time ago, a "committee to prevent misleading food propaganda and false health standards" was formed. Representatives of agriculture, the food products industries and scientific bodies united to combat the adulteration of agricultural products and the contamination of curative agents, food products and articles of luxury. It is not intended to create a new organization but to effect an amalgamation of the various fields of activity and their representatives. Of the many tasks that the committee has assumed may be mentioned publicity campaigns to convince the people of the high grade and excellent quality of German products in general. Attention was called to the fact that great harm is being caused by manifestations of pseudoscience and so-called reform movements of an exaggerated character. In addition to carrying on publicity campaigns, the committee plans to place the needed information before the authorities and to promote such legislation as will control the evils mentioned.

Exchange of Information on Communicable Diseases

An agreement has been reached concerning the exchange of information on communicable diseases along the frontier between Germany and Czechoslovakia. In order that prompt action may be taken to prevent the transmission of disease, a regular exchange of news items concerning diseases of an epidemic character is to be established. The German centers will transmit weekly reports and the centers in Czechoslovakia will send out semimonthly reports, with exact statements as to time and place and the measures that have been adopted to prevent dissemination of disease. The sending of health officers to a stricken area must be announced in advance to the other state, and no significant action may be taken by one state except in the presence of an officer of the other state.

PRAGUE

(From Our Regular Correspondent)

May 27, 1933.

Propedeutic Clinics

Professor Prusik held recently his inaugurating lecture as the new chief of the propedeutic clinic of the Czech faculty of medicine of Prague. The propedeutic clinics have been organized because of a need for a place where students could obtain thorough instruction in diagnostic methods before they enter the different clinical departments of the faculty of medicine. The diversity of complicated diagnostic methods used in the clinical examination today makes it necessary for students to acquire a thorough preliminary knowledge of them, if they are to succeed in the specialized clinics. The need is specially urgent, since the medical faculties are overfilled with students and clinical departments are short of material for demonstration purposes. They cannot slow up the work by demonstrations of elementary diagnostic technic, which can be mastered only through patient and skilful teaching. Propedeutic clinics are still in an experimental stage and the field of activity in relation to other subjects must be worked out.

The Mental Hygiene Movement

The mental hygiene movement in Czechoslovakia is gaining ground slowly. This movement can be traced directly to the stimulus of the Washington world conference on mental hygiene. Following this conference a mental hygiene board was created under the presidency of the minister of health and a monthly periodical was started. A league of mental hygiene was organized, which conducted recently a nationwide mental hygiene week to call the attention of the public to the importance of mental hygiene.

The response shown by the public to this drive seems to have satisfied its organizers.

Report of Committee on Sickness Insurance

The official committee appointed by the ministry of social welfare to draw up a scheme to reform the social insurance system has presented its final report. The committee was called into being because of the unfavorable financial situation in which the sickness insurance funds found themselves. The committee states that the embarrassing situation of the insurance system was mainly caused by the depression and therefore the measures recommended for improving the financial situation can be regarded as transitory. The report did not recommend any curtailment of medical benefits. The economies recommended concern financial benefits. The report tries to eliminate as much as possible the sickness of short duration from the insurance scheme. If the sickness lasts less than four days the insured have no right to any financial support. Up to the present, the financial benefit in case of sickness amounted to two thirds of the average wage. The report recommends decreasing the financial aid to one half of the wage in case of sickness of short duration. This period varies according to the financial strength of the insurance fund. While the sickness insurance bodies are in an unfavorable financial position this does not hold for the invalidity and old age insurance, so the report attempts to place a part of the burden of chronic diseases on the invalidity insurance. The report suggests some administrative changes which might result in economies. No profound changes in the whole system have been recommended by the committee, and it regards the suggested measures as transitory.

Red Cross Conference

A conference of the Central European Societies of the Red Cross was held in Prague in April. Representatives of many nations attended. It was emphasized in the report that the development of nursing in central Europe has progressed so far

that public authorities will have to create a legal background for further growth by making acceptable conditions for nurses working in the hospitals. The Red Cross can open the way for official action. Even the small countries have been successful in this direction. It was pointed out that the best way to improve the working conditions among the nurses is to give them a better education so they can develop for themselves their working conditions within the community. Only a thorough nursing education makes it possible for the home visitor to interpret correctly the situation in the home. The conference was presided over by Dr. A. G. Masaryk, daughter of the president of the republic, and was addressed by Dr. F. Spina on behalf of the Czechoslovakian government.

A Study of Abortions

The results of an investigation on the frequency of abortions in Czechoslovakia was recently presented to a medical audience by Dr. H. Hecht. The report was based on a questionnaire filled out through a direct interview with some thirteen hundred married women. About one third of the questionnaires dealt with women from Greater Prague, the remaining two thirds with women from rural areas. The data show that there is only a slight preponderance of births over the number of abortions in this group, and that abortions were about as frequent in the rural areas as in Prague. About 67 per cent of the married women admitted having had an abortion at some time. Women of middle age confessed on the average 3.8 abortions in Prague, 3.5 in rural territories. There was an average of 3.5 abortions for women of 30 years of age. Women older than 30 admit on the average 4.7 abortions. Five per cent of the women have never given birth to a living child, although they had had several abortions. The report does not attempt to separate the abortions into those due to natural causes and those which were artificial. The study disclosed cases in which three abortions occurred in one woman in one year and the total number of abortions was forty. In many cases, artificial abortions are being carried out by the women themselves.

RIO DE JANEIRO

May 15, 1933.

Rapid Cholecystography

Dr. Eduardo Cotrim presented before the Paulist Association of Medicine, January 20, a study of cholecystography by means of tetiothalein sodium. He concludes that the best results are obtained by an intravenous injection of 125 cc. of a 40 per cent solution of dextrose ten minutes after the tetiothalein has been given in the usual dose, dissolved in 40 cc. of distilled water and followed by 25 units of insulin subcutaneously. The gallbladder becomes visible from one and one-half to two hours later. He discusses the mechanism of the procedure, demonstrating the part that dextrose plays. He concludes with a study of the advantages of the Antonuci method over that of Graham.

Roentgenographic Study of the Mastoid

Dr. Mangabeira Albernaz, in a communication to the Paulist Association of Medicine, January 17, stated that a roentgenographic study of the mastoid may be made from a strictly roentgenologic point of view or it may take on a special clinical character. From the latter point of view, bilateral exposures are preferred and one of the most useful and simple methods is the posterior occipital of Worms-Bretton-Altschul. The author showed thirty films. The similarity of structure between the right and left mastoid of the same person is the basis of the bilateral method for comparison. Some authors deny this similarity as well as the value of bilateral exposures. The author made a roentgenographic study of 100 pairs of temporal bones and concluded that only in 1 per cent of the cases was

there a distinct difference between the two mastoids (*Annaes paulistas de medicina e cirurgia*, March, 1933).

Bacillus Proteus XL and Exanthematous Typhus

Dr. J. Carvalho Lima read before the Society of Medicine and Surgery of São Paulo, February 1, his correspondence with Professor Felix of the Lister Institute of London on the new species of *Bacillus proteus* X, which he isolated in São Paulo and which, as proposed by Professor Felix, is designated species XL (strain Lima). Studies made at the Bacteriologic Institute of São Paulo and at the Lister Institute of London demonstrate that the serum of patients suffering from the exanthematous typhus of São Paulo possesses agglutinins primarily for proteus XL and secondarily for proteus XK. Professor Felix believes that strain XL is the type that corresponds antigenically to the species of exanthematous typhus of São Paulo.

Blood Sedimentation in Pulmonary Tuberculosis

In an article in the March issue of the *Revista brasileira de tuberculose*, Dr. Lincoln Ferreira Faria draws the following conclusions based on about 1,000 experiments:

1. Various causes may affect the sedimentation rate.
2. Collecting blood for the sedimentation test must be done always at the same hour, preferably in the morning, before or after a light breakfast, which must always be equal in kind and quantity.
3. In making a sedimentation test on women, menstruation must be considered; the blood must be taken six or seven days before or four or five days after the menstrual period.
4. The exudative and pleural forms of tuberculosis with effusion cause an increased rate of sedimentation; the fibrous and some stationary ulcerating forms produce little or no change in the sedimentation rate.

NETHERLANDS

(From Our Regular Correspondent)

May 13, 1933.

The Congress on Midwifery

A number of scientific congresses were held at Ghent from March 31 to April 4. The congress on midwifery was presided over by Professor Daels and was attended by delegates from the Netherlands, France, Germany, England, Denmark, Czechoslovakia, Switzerland, Poland, Bulgaria, Lithuania, Austria and Hungary. In addition, numerous lectures in various branches of medicine were given. Professor Heymans of Ghent reported the results of his research on the vasomotor regulation of the circulation. Dr. Tytgat of Ghent discussed acute cholecystitis and compared this disorder with acute appendicitis. Dr. Wenckebach presented a communication on the mechanism of sudden death due to beriberi. During a recent journey in the Orient, he had an opportunity to observe several cases of beriberi in which sudden death was sometimes brought about by cardiac dilatation. These congresses, which are held every two years, furnish evidence of the scientific activity of the Flemish people.

The Dutch Association of Colonial Medicine

Two interesting topics were discussed at the meeting of the Netherlands association of colonial medicine: the El Tor vibrio and the possible identity of frambesia and syphilis. It was held that there is a difference between the vibrio of cholera and the El Tor vibrio. The latter is hemolytic, whereas in all vibrios isolated from cholera patients the hemolytic capacity has been absent. Dr. Kayser, who discussed the identity of frambesia and syphilis, found that a crossed immunity toward the two disorders may exist. From a study of the research of Koile, Chesney, Kemp, Nichols and Reasoner, he concludes that the differences found between the two diseases are more of a quantitative than a qualitative nature and are not sufficient to establish a distinction between them.

Marriages

CHESTER HERBERT BOWERS, Los Angeles, to Mrs. Isabel Hayner Thompson of Beverly Hills, Calif., June 14.

WARREN E. ANDERSON to Miss Sophie Lee, both of Pensacola, Fla., at Nashville, Tenn., June 10.

CHARLES WESLEY EISELE, Naperville, Ill., to Miss Blanche Mae Kennell of Rochester, Ind., June 15.

DANIEL LESLIE ROTHCHILD to Miss Dorothy Goodman, both of Newark, N. J., May 25.

SYLVESTER E. LENTZ, Leighton, Pa., to Miss Esther Lorene Guyer of Philadelphia, June 14.

RUDOLPH M. ZODIKOFF, Cincinnati, to Miss Dolores Utrecht of Charleston, W. Va., June 7.

LEONEL L. KAHN, Rayne, La., to Miss Emeline Weill of Abbeville, June 11.

MAY ROBERT MORROW, Seattle, to Miss Janice Heuston, May 18.

WALLACE D. HUNT, Seattle, to Miss Irene Shenkle, June 1.

Deaths

Richard Travis Atkins ☉ New York; University and Bellevue Hospital Medical College, 1906; professor of otolaryngology at his alma mater; formerly assistant professor of otolaryngology, Columbia University College of Physicians and Surgeons; member of the American Otological Society; fellow of the American College of Surgeons; served during the World War; surgeon in charge of the ear, nose and throat department, Bellevue Hospital; surgeon to the New York Eye and Ear Infirmary; consulting otolaryngologist to the Hackensack (N. J.) Hospital and the North Country Community Hospital, Glen Cove, N. Y.; aged 49; died, June 27, in the Massachusetts General Hospital, Boston.

Eugene G. Northington ☉ Lieut. Colonel, U. S. Army, retired, Birmingham, Ala.; Tulane University of Louisiana Medical Department, New Orleans, 1903; entered the medical corps of the U. S. Army as a first lieutenant in 1911 and rose through the various grades to that of lieutenant colonel in 1930 when he retired for disability in line of duty; fellow of the American College of Surgeons; aged 53; died, June 9, in the Letterman General Hospital, San Francisco, as a result of roentgen-ray burns received twenty-four years ago.

Max Goltman ☉ Memphis, Tenn.; University of Bishop College Faculty of Medicine, Montreal, 1892; professor of surgery, University of Tennessee College of Medicine; president of the Memphis and Shelby Counties Medical Society; fellow of the American College of Surgeons; president of the department of health, 1910-1914; surgeon to the Baptist Memorial, Memphis General and Woman's hospitals; aged 66; died, June 17, of heart disease.

Ewing Fox Howard ☉ Vicksburg, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1897; member of the House of Delegates of the American Medical Association in 1916; past president of the Mississippi State Medical Association; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Vicksburg Hospital; aged 59; died, June 8.

Henry Perry Jackson ☉ Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1897; formerly demonstrator in histology, pathology and bacteriology at his alma mater; past president of the South Carolina Medical Association, and the Charleston County Medical Society; aged 70; on the staff of the Roper Hospital, where he died, June 4.

George Edwin Steel ☉ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886; member of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; aged 69; died, June 12, in a hospital at Waterbury, Conn., of cerebral hemorrhage.

Walter David Moceabee, Cardington, Ohio; Ohio Medical University, Columbus, 1897; veteran of the Spanish-American and World wars; for many years a member and at one time president of the board of education; aged 58; died, June 5, in the Mount Carmel Hospital, Columbus, following an operation for appendicitis.

Frank Emil Nagel ☉ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; acting assistant surgeon, U. S. Public Health

Service; aged 57; died, June 20, in the U. S. Marine Hospital, of acute appendicitis and diabetes mellitus.

John Dooley Mauldin, Gainesville, Ga.; University of Georgia Medical Department, Augusta, 1901; member of the Arizona State Medical Association; served during the World War; aged 57; died, June 6, in Atlanta, Ga., of cardiorenal vascular disease and arteriosclerosis.

George J. Hermann, Newport, Ky.; Medical College of Ohio, Cincinnati, 1894; member of the Kentucky State Medical Association; member of the board of trustees of the Speers Memorial Hospital, Dayton; aged 59; died, June 8, of coronary thrombosis and chronic nephritis.

Russell Dunson Elliott, Provincetown, Mass.; Harvard University Medical School, Boston, 1873; member of the Massachusetts Medical Society; formerly member of the school committee of Boston and police surgeon; aged 84; died, May 21, of valvular heart disease.

William Sylvester Royce, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1897; on the staff of the West-side Hospital; aged 70; died, June 8, of cerebral hemorrhage and diabetes mellitus.

Albin Monroe Painter, Kansas City, Mo.; St. Louis University School of Medicine, 1905; member of the American Academy of Ophthalmology and Oto-Laryngology; aged 52; on the staff of the Research Hospital, where he died, May 19, of heart disease.

William Rounds, Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1903; member of the State Medical Association of Texas; aged 64; died, May 22, of intestinal hemorrhage and paralysis agitans.

Hugh M. Milstead, Hornsby, Tenn.; Memphis Hospital Medical College, 1899; member of the Tennessee State Medical Association; formerly mayor of Hornsby; bank president; aged 68; died, June 2, in Jackson, of gastric ulcer.

Frank Grosvenor Parkhill, Houston, Texas; National Medical University, Chicago, 1903; Hahnemann Medical College and Hospital, Chicago, 1906; served during the World War; aged 64; died, June 4, of general cachexia.

Joseph Howard Campbell, Bismarck, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; served during the World War; aged 60; died, May 30, of coronary sclerosis.

Clifford M. Sherron, Salem, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1879; member of the Medical Society of New Jersey; bank president; aged 77; died, June 11, of carcinoma of the prostate.

William S. Rambo, Rochester, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1889; aged 69; on the staff of the Genesee Hospital, where he died, June 9, of coronary thrombosis and chronic nephritis.

Arthur F. Rykert, Dundas, Ont., Canada; University of Toronto Faculty of Medicine, 1893; county coroner; formerly member of the legislature of Ontario; aged 63; died, May 30, in a hospital at Toronto, of heart disease.

John Bloss Wolfe, Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1915; served during the World War; on the staffs of the Wilkes-Barre General Hospital; aged 41; died suddenly, June 1, of heart disease.

William H. Ratcliff, New Albany, Ind.; Southwestern Homeopathic Medical College and Hospital, Louisville, Ky., 1906; member of the Indiana State Medical Association; aged 72; died, June 12, of heart disease.

Adolph Joseph Lieber, Des Moines, Iowa; University of Louisville (Ky.) School of Medicine, 1889; formerly city health commissioner; aged 68; died, May 25, of carcinoma of the intestine and liver.

Frederick Austin Mandeville, Rochester, N. Y.; University of Buffalo School of Medicine, 1875; member of the Medical Society of the State of New York; aged 79; died, May 26, of heart disease.

Samuel J. Rose, Lexington, Ky.; Jefferson Medical College of Philadelphia, 1912; served during the World War; aged 46; died, June 12, in the Good Samaritan Hospital, of an overdose of a sedative.

Gennaro Merolla, Brooklyn; Regia Università di Napoli; Facoltà di Medicina e Chirurgia, 1883; member of the Medical Society of the State of New York; aged 80; died, June 1, of heart disease.

William Haverfield Taylor, Youngstown, Ohio; Rush Medical College, Chicago, 1902; aged 56; died, June 1, in the

Northside unit of the Youngstown Hospital, of carcinoma of the liver.

Marshall H. Stephens, Bremen, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893; formerly mayor of Bremen; aged 70; died, May 6, of intestinal obstruction.

Reuben D. Whisler, Findlay, Ohio; Baltimore Medical College, 1892; formerly county coroner; on the staff of the Home and Hospital; aged 66; died, June 14, of heart block.

Nathan D. Woodard, Indianapolis; Physio-Medical College of Indiana, Indianapolis, 1879; member of the Indiana State Medical Association; aged 83; died, June 8, of pneumonia.

Adrian Hava, New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1884; aged 69; died, May 29, of bronchopneumonia and dilatation of the heart.

Mary M. Van Nuys, Lebanon, Ind.; Northwestern University Woman's Medical School, Chicago, 1897; aged 71; died, May 26, of cerebral hemorrhage and chronic myocarditis.

James Edward Maxwell, Decatur, Mich.; University of Michigan Medical School, Ann Arbor, 1892; aged 68; died, June 11, of injuries received in an automobile accident.

Ralph L. Waters, Lakeside, Ohio; Western Reserve University Medical Department, Cleveland, 1883; aged 73; died, May 5, at Bloomington, Ill., of organic heart disease.

Alfred Waldemar Herzog, New York; University of the City of New York Medical Department, 1887; aged 67; died, May 30, of hypertension and cerebral hemorrhage.

Dellah M. Wells, Providence, R. I.; Dartmouth Medical School, Hanover, N. H., 1883; aged 72; died, May 25, of diabetes mellitus, arteriosclerosis and nephritis.

Joseph R. Appelbe, Saginaw, Mich.; Saginaw (Mich.) Valley Medical College, 1902; aged 67; died, June 5, of cardiac insufficiency following gallbladder colic.

Ralph Franklin Hodgdon, Somerville, Mass.; Tufts College Medical School, Boston, 1902; aged 53; was found dead, May 7, of a self inflicted bullet wound.

William Oscar Warren, Carlyle, Ill.; St. Louis University School of Medicine, 1915; served during the World War; aged 42; was found dead, May 30.

Henry Adams, Embro, Ont., Canada; Eclectic Medical College of Pennsylvania, Philadelphia, 1864; Civil War veteran; aged 98; died in May, at Toronto.

Ernest George Aston, Port Washington, Wis.; Marquette University School of Medicine, Milwaukee, 1924; aged 36; died, June 2, of heart disease.

Charles R. Wells, Wauconda, Ill.; University of Michigan Medical School, Ann Arbor, 1866; aged 88; died, May 6, at Crystal Lake, of myocarditis.

George King Pratt, Jr., New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1906; aged 49; died, June 9, of heart disease.

Omar Matthew Wilson, Ottawa, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1904; aged 52; died suddenly, May 19.

Robert Perry Cummins, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1901; aged 58; died, May 30, of heart disease.

Orley H. Murphy, Lincoln, Ill.; Chicago College of Medicine and Surgery, 1917; aged 65; was killed, May 19, in an automobile accident.

William S. Sproles, Bluff City, Tenn.; Chattanooga (Tenn.) Medical College, 1898; aged 63; died, June 6, of carcinoma of the prostate.

Walter M. Friend, Brooklyn; Harvard University Medical School, Boston, 1884; aged 63; died, May 31, of cerebral hemorrhage.

Garrett Fitzgibbon, Chicago; Rush Medical College, Chicago, 1889; aged 76; died, June 3, of carcinoma of the gallbladder.

Silas Wright Hurd, Lockport, N. Y.; Hahnemann Medical College of Philadelphia, 1880; aged 76; died, June 7, of heart disease.

George W. Pickering, Urbana, Ohio; Starling Medical College, Columbus, 1886; aged 73; died, June 7, of heart disease.

R. W. Harris, Algiers, Ind.; Kentucky School of Medicine, Louisville, 1877; aged 84; died, June 8, of cerebral hemorrhage.

John W. Speight, Roper, N. C.; Kentucky School of Medicine, Louisville, 1885; aged 67; died, June 23, of heart disease.

George W. Stanton, Athens, Tenn. (licensed, Tennessee, 1902); aged 71; died, June 12, of cardiac decompensation.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[Editorial Note: The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Femalga Capsules.—D'Ormont Laboratories, Philadelphia. Composition: Amidopyrine, 2.6 grains to each capsule. For painful menstruation, etc. Fraudulent therapeutic claims.—[N. J. 18368; February, 1932.]

Means' Pills.—W. B. Means, Lebanon, Pa. Composition: Acetanilid, caffeine, camphor and strychnine. For rheumatism, female disorders, etc. Fraudulent; acetanilid content wrongly declared.—[N. J. 18369; February, 1932.]

Meth-O-Sal.—Kelvan Co., Philadelphia. Composition: Methyl salicylate, oil of camphor, petrolatum and paraffin. For rheumatism, pneumonia, neuritis, etc. Fraudulent therapeutic claims.—[N. J. 18376; February, 1932.]

Seven Oraps.—Sbafer Pharmacal Co., Philadelphia. Composition: Sodium salicylate and water, colored and flavored. For rheumatism, kidney and bladder troubles, etc. Fraudulent therapeutic claims.—[N. J. 18377; February, 1932.]

Kline's Rheumatic Remedy.—H. E. Kline, Philadelphia. Composition: Sulphur (63 per cent), glycerin, flavored with methyl salicylate. Fraudulent therapeutic claims.—[N. J. 18378; February, 1932.]

Laxative 9 to 9 Health.—9 to 9 Pharmacal Co., Philadelphia. Composition: Quinine sulphate, epsom salt, iron (ferrie) chloride and water. For liver and kidney disorders, etc. Fraudulent therapeutic claims.—[N. J. 18379; February, 1932.]

Phyllosan.—Lightfoot and Schulz Co., New York City. Composition: Chlorophyll and compounds of calcium, aluminum and iron. For anemia, high blood pressure, etc. Fraudulent therapeutic claims.—[N. J. 18381; February, 1932.]

Nestar Emulsion of Cod-Liver Oil.—Nestor Drug and Chemical Co., Chicago. Composition: Cod-liver oil (about 40 per cent), small quantities of calcium and sodium hypophosphites, egg yolk, phosphoric acid, alcohol (8.4 per cent) and water. Flavored with methyl salicylate. For pulmonary disorders, etc. Fraudulent therapeutic claims.—[N. J. 18384; February, 1932.]

Hays' Specific.—Kolb Bros. Drug Co., Paducah, Ky. Composition: Small quantities of ammonium and iron sulphates and sulphuric acid, with a laxative plant drug, alcohol and water. Cure-all. Fraudulent therapeutic claims.—[N. J. 18387; February, 1932.]

Williams' (G. B.) Liver and Kidney Pills.—Interstate Drug Co., Quitman, Ga. Composition: A compound of mercury such as calomel, aloe, and a resin such as podophyllum resin, a trace of an alkaloid. Fraudulent therapeutic claims.—[N. J. 18388; February, 1932.]

Moore's Herb Bitters.—Moore Drug Co., Hot Springs, Ark. Composition: Sodium salicylate, a laxative plant drug and water. Cure-all. Fraudulent therapeutic claims.—[N. J. 18390; February, 1932.]

Hinkaps.—Hinkle Capsule Co., Inc., Mayfield, Ky. Composition: Capsules containing iron (ferrie) chloride, calcium carbonate, cubeb oil, extracts of plant drugs and talc. For kidney disorders. Fraudulent therapeutic claims.—[N. J. 18393; February, 1932.]

Kobala Tonic.—M. J. Weiskopf, Chicago. Composition: Iron citrate, methenamine, laxative plant drug, alcohol and water. Cure-all. Fraudulent therapeutic claims.—[N. J. 18395; February, 1932.]

Tiko.—Kells Co., Newburgh, N. Y. Composition: Potassium iodide, alcohol, water and a trace of colchicine. For rheumatism, etc. Fraudulent therapeutic claims.—[N. J. 18396; February, 1932.]

Waad's Fever Pills.—Wm. Wood and Sons, Cairo, Ill. Composition: Acetanilid (0.86 grain per pill), cinchonine and a laxative plant drug. Fraudulent therapeutic claims.—[N. J. 18400; February, 1932.]

Vaca.—Voght Laboratories, Escanaba, Mich. Composition: Extracts of plant drugs, sugar, glycerin, alcohol, water and a small quantity of ammonium chloride. For influenza, asthma, hay fever, etc. Fraudulent therapeutic claims.—[N. J. 18453; March, 1932.]

Murmann's Compound.—D. W. Price Co., Toledo, Ohio. Composition: Wood creosote, sugar, water and a small quantity of an iron compound. Bronchitis, asthma, etc. Fraudulent therapeutic claims.—[N. J. 18460; March, 1932.]

PX.—PX Products, Inc., Detroit. Composition: Salt, aluminum chloride, zinc sulphate and water. For eczema, etc. Not germicidal. Fraudulent therapeutic claims.—[N. J. 18470; March, 1932.]

Triner's Cold Tablets.—William A. Webster Co., Memphis, Tenn. Composition: Acetanilid (0.96 grains per tablet), quinine (0.34 grains per tablet), and podophyllum resin. Fraudulent therapeutic claims.—[N. J. 18472; March, 1932.]

Cerevisine Tablets.—E. Fougere and Co., Inc., New York. Composition: Essentially dried yeast. For diabetes. Fraudulent therapeutic claims.—[N. J. 18475; March, 1932.]

Arex.—Arex Products Corporation, Brooklyn, N. Y. Composition: Aspirin, caffeine, charcoal, a bismuth compound, corn starch and talc. For headache, rheumatism, neuralgia, etc. Fraudulent therapeutic claims.—[N. J. 18479; March, 1932.]

Wagner's Tonic and Stamaehie.—A. L. Wagner and Co., North Chicago, Ill. Composition: Extracts of bitter plant drugs, glycerin, alcohol (about 20 per cent by volume) and water. Alcohol content falsely declared. Fraudulent therapeutic claims.—[N. J. 18481; March, 1932.]

Sassafala.—Sassafala Manufacturing Co., Elmira, N. Y. Composition: A petrolatum ointment with menthol, eucalyptol and methyl salicylate. For catarrh, pneumonia, rheumatism, etc. Fraudulent therapeutic claims.—[N. J. 18483; March, 1932.]

Korathein.—Georgian Pharmacal Co., Atlanta, Ga. Composition: Acetphenetidin (1.12 grains to the capsule), phenolphthalein, caffeine, camphor, a calcium compound and a salicylate. For influenza, neuralgia, etc. Fraudulent therapeutic claims.—[N. J. 18484; March, 1932.]

Rice's G. G. Liniment.—Rice Chemical Co., Greensboro, N. C. Composition: Turpentine oil, ammonia, an emulsifying agent, and water. Fraudulent therapeutic claims.—[N. J. 18486; March, 1932.]

Hill's Rheumatic and Gout Remedy.—Hill Products Co., Orange, N. J. Composition: Potassium acetate, suspended vegetable matter and 91 per cent water. Fraudulent therapeutic claims.—[N. J. 18487; March, 1932.]

Clay's Rheumatic Medicine.—E. J. Kieffer, Savannah, Ga. Composition: Colchicine, potassium iodide, a nitrite and extracts of plant drugs. Fraudulent therapeutic claims.—[N. J. 18492; March, 1932.]

Devore Laxative Cold and Grippe Tablets.—Devore Manufacturing Co., Columbus, Ohio. Composition: Acetanilid (2 grains to the tablet), cinchona alkaloids, camphor, aloe and extracts of plant drugs. Fraudulent therapeutic claims.—[N. J. 18494; March, 1932.]

A. P. C. Laxative Quinine Cold Tablets.—American Pharmaceutical Co., New York City. Composition: In each tablet, acetanilid (about 1½ grains), quinine sulphate, caffeine, monobromated camphor and an extract of a laxative plant drug. Fraudulent therapeutic claims.—[N. J. 18498; March, 1932.]

Phosphorein.—Eimer and Amend, New York. Composition: Calcium and sodium glycerophosphates, phosphoric acid, nux vomica and glycerin. Nerve tonic. Fraudulent therapeutic claims.—[N. J. 18499; March, 1932.]

Hien Fong Essence.—Knorr Medical Co., Detroit, Mich. Composition: Oils of spearmint, peppermint and camphor, a small quantity of ether with extracts of plant drugs, alcohol (52.5 per cent by volume) and water. Cure-all. Alcohol content wrongly declared. Fraudulent therapeutic claims.—[N. J. 18502; March, 1932.]

Cystogen Aperient.—Cystogen Chemical Co., Brooklyn. Composition: Sodium phosphate (51.4 per cent) and methenamine (7.8 per cent), baking soda, citric acid and tartaric acid. "Internal antiseptic." Fraudulent therapeutic claims.—[N. J. 18504; March, 1932.]

Cystagen Lithia.—Cystogen Chemical Co., Brooklyn. Composition: In each tablet, methenamine (3 grains), lithium tartrate (2.9 grains), baking soda, citric acid and tartaric acid. For gout, rheumatism, diabetes, etc. Fraudulent therapeutic claims.—[N. J. 18504; March, 1932.]

Oxien Nazane Salve.—Giant Oxie Co., Augusta, Me. Composition: A petrolatum ointment with sassafras oil, camphor and methyl salicylate and traces of carbolic acid and menthol. Cure-all. Fraudulent therapeutic claims.—[N. J. 18505; March, 1932.]

Vernas.—Vernas Chemical Co., Paterson, N. J. Composition: Zinc chloride, glycerin, alcohol (23.2 per cent by volume) and water, flavored with cinnamon and peppermint oils. Not antiseptic. "Feminine hygiene douche." Fraudulent therapeutic claims.—[N. J. 18508; March, 1932.]

Po-Me-Ka.—Rex Chemical Co., Inc., Waynesboro, Pa. Composition: Oil with a stearic acid base containing boric acid, a potassium compound, carbolic acid, glycerin and oils of menthol, camphor and pine. For influenza, pneumonia, etc. Fraudulent therapeutic claims.—[N. J. 18509; March, 1932.]

Edwards' Compound Oandelion Tablets.—Relief Laboratory, Inc., Newburgh, N. Y. Composition: Extracts of plant drugs including cathartics such as aloe and jalap resin. For rheumatism, etc. Fraudulent therapeutic claims.—[N. J. 18512; March, 1932.]

Red Pills.—Joseph Triner Co., Chicago. Composition: Aloe, strychnine and ginger oleoresin. For indigestion, female troubles, rheumatism, etc. Fraudulent therapeutic claims.—[N. J. 18514; March, 1932.]

Palmiaed.—Simmon Co., Cleveland. Composition: Capsules containing a fatty substance, creosote and water. Falsely claimed to be germicidal and antiseptic. For tuberculosis, etc. Fraudulent therapeutic claims.—[N. J. 18517; March, 1932.]

Pierre's Hygeiafarms.—Pierre Chemical Co., Chicago. Composition: Boric acid, zinc sulphate and a quinoline derivative. Falsely claimed to be germicidal and antiseptic. For leucorrhea, etc. Fraudulent therapeutic claims.—[N. J. 18521; March, 1932.]

Duncan's Owl Tonic.—Duncan Chemical Co., St. Louis. Composition: Epsom salt, quinine sulphate, citric acid, a small quantity of iron chloride, and water. For influenza, malaria, etc. Fraudulent therapeutic claims.—[N. J. 18522; March, 1932.]

Lana Fume Pneumonia Salve.—McKesson-Stewart-Holmes Drug Co., Seattle. Composition: Volatile oils including eucalyptus oil, camphor and ammonia in a base of wool fat. Fraudulent therapeutic claims.—[N. J. 18524; March, 1932.]

Hooper's Tettremidy.—Eucaline Medicine Co., Dallas, Tex. Composition: Acetic acid (17 per cent), glycerin (29 per cent) with traces of arsenic and iron compounds, and water. For eczema, etc. Fraudulent therapeutic claims.—[N. J. 18527; March, 1932.]

Fem Tonic.—McKesson-Merrell-St. Louis Drug Co., St. Louis. Composition: Nux vomica, a laxative drug, a small quantity of salicylic acid, and sugar, alcohol and water. A tonic for "female organs." Fraudulent therapeutic claims.—[N. J. 18528; March, 1932.]

Correspondence

TERPEZONE

To the Editor:—Terpezone, Inc., is distributing a circular advertising "Terpezone," in which it quotes various favorable statements ascribed to different individuals. Among these is one made by me nearly twenty years ago (1914).

It is true that, in 1913, a limited personal experience with Terpezone, reinforced by the enthusiasm of an assistant in whom I placed much confidence, led me to ascribe favorable results in cases that more mature judgment might explain on the basis of autosuggestion. I stopped the use of Terpezone inhalation after a sufficient trial had convinced me of its lack of value. For many years I have not considered it of any importance as a therapeutic agent.

S. ADOLPHUS KNOPE, M.D., New York.

[NOTE.—After examination of the evidence on Terpezone as a remedy in pulmonary tuberculosis, the Council on Pharmacy and Chemistry of the American Medical Association authorized the publication of a lengthy report in THE JOURNAL, April 14, 1928. The report concludes as follows:

"The information presented in favor of Terpezone certainly does not establish its identity, purity or its therapeutic value. The Council is therefore obliged to declare Terpezone unacceptable for New and Nonofficial Remedies because no satisfactory evidence is presented to show that Terpezone is pinene ozonide or that in the manufacture of the product the formation of injurious by-products is controlled or prevented; because the claimed harmlessness of the product is not established, and because it is marketed with unwarranted and exaggerated claims of therapeutic value."—ED.]

MALARIA TRANSMITTED BY HYPODERMIC SYRINGE

To the Editor:—In regard to the article in THE JOURNAL, May 6, by Dr. O. C. Nickum on "Malaria Transmitted by Hypodermic Syringe," I should like to add this:

There have been about twelve cases in the past year at this institution of malaria, proved by finding the organisms in the blood, in morphine addicts who took the drug intravenously. The first case I saw in April, 1932, and this addict stated that the condition was due to the fact that he had used another addict's syringe in taking a dose intravenously. He also stated that, as long as the user did not take the drug intravenously, he did not develop malaria. Recently there were six such cases in the Men's Building here, and four of them were in Dr. Samuel N. Feinberg's service. All of these patients belong to the same group of addicts, although they would not admit the fact, and passed the syringe round to each one, each taking an intravenous dose. This apparently is a common practice among morphine addicts.

It has reached a point at which many of the interns here, who see a patient that has thrombotic basilar veins and gives a history of intermittent chills and fever occurring at regular intervals, usually make a diagnosis of malaria in a morphine addict in the examining room.

NATHAN FLAXMAN, M.D., Chicago.

Senior Intern, Cook County Hospital.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ALLERGY TO FOODS AND MIGRAINE

To the Editor:—I have under my care a man who for years has suffered from severe headaches, which I think are caused by food allergy. I have not the means for testing him for sensitivity to various substances, but for the past three weeks I have had him on elimination diets 1, 2 and 3, as described by Rowe in his book "Food Allergy," with almost complete relief from symptoms. Whereas formerly never a day went by without a headache, now the headaches occur at weekly intervals. Is it probable that there is some food to which he is mildly sensitive that he is still taking in his diet? What is your opinion as to the use of 5 per cent Armour's peptone solution in such cases? Please describe the technic for preparing this solution. Is epinephrine of any value for the relief of headaches due to allergic migraine? Please omit name and address.

M.D., Texas.

ANSWER.—The relief obtained from elimination diets 1, 2 and 3 favors food allergy as a cause of the headaches. With a continued use of these diets the remaining headaches may disappear, since at times from two to four weeks is necessary before the reacting allergens are entirely eliminated from the sensitized tissue cells. The headaches may be recurrent because the patient is not 100 per cent strict in adhering to his diet. It is also possible that some foods in the elimination diets he is taking are productive of mild allergies. Such mild allergies may be suspected at times through the patient's history of food dislikes or disagreements. A food diary as suggested by Vaughan may help. One or two of the separate elimination diets might be tried, or supplemental trial diets outlined by Rowe can be used. Of these his cereal-free elimination diet is of special value.

Rowe (Food Allergy, Philadelphia, Lea & Febiger, 1931) has emphasized that diets based on skin reactions, and personal histories of food dislikes or disagreements, may relieve food allergy. This has been substantiated by Vaughan, Eyer mann, Balyeat and others. However, positive skin reactions and personal histories of possible food allergies do not always denote clinical food sensitizations. Moreover, food allergy frequently exists without satisfactory scratch or intradermal skin reactions. The elimination diets according to Rowe should be modified by the substitution of similar foods for any in the diets to which definite skin reactions are obtained or for which a history of dislikes or disagreements exists. And when patients cannot be skin tested because of expense or distance from physicians qualified to do such testing, the use of "elimination diets" is justifiable.

It must be emphasized that several modifications of the "elimination diets" have been suggested and that diet trial may be carried out by other methods. However, the elimination diets of Rowe are standardized and are in wide use today and if used according to directions assure proper caloric, vitamin and mineral intake, so that nutritional damage will not occur.

Armour's 5 per cent peptone can be purchased in sterile ampules. When given intravenously it is of value in a few cases; but severe shock reactions contraindicate its use, and its effects are not lasting. Elimination of allergic foods is much more effective. Epinephrine may relieve some patients with allergic migraine, but it is not so effective as in bronchial asthma or urticaria.

TINEA CAPITIS

To the Editor:—Is there any new preparation for the local treatment of tinea capitis? Occasionally people object to either thallium or x-rays. I am well acquainted with the treatments as given by Hubbard, Hartzell, McLeod, Sequeira and Andrews. Is the medicated gutta percha a success? It is reported on both ways. Also the ethyl chloride. I have not tried either one, and both have been reported on favorably. Please omit name.

M.D., Canada.

ANSWER.—An uncertain percentage of cases of ringworm of the scalp will yield to milder measures than roentgen rays or thallium acetate. This percentage varies with the virulence of the organism and the resistance of the patient. It is always justifiable to try the milder measures before resorting to the more regularly effective but more dangerous ones.

The gutta percha method of Kingery, from the warning given to cease treatment on irritation, is fairly strong treatment. The ethyl chloride treatment has been found more troublesome to apply and less efficient than the old fashioned ointment method.

E. P. Lieberthal (Treatment of Microsporon Infection of the Scalp, *Arch. Dermat. & Syph.* 18:97 [July] 1928) has combined the use of a 5 per cent aqueous solution of mercuriochrome, painted on every other day, with the use of 10 per cent ointment of ammoniated mercury, with success in a fair percentage of cases. Another well tried method not often mentioned is the production of dermatitis venenata in the infected areas by the successive application of tincture of iodine and ointment of ammoniated mercury. This should be tried on a small area first to judge its intensity and should not be repeated on the whole area infected until the reaction from the first application has fully subsided. The superficial infections with microsporon and other forms of fungus are persistent because they do not arouse a reaction in the tissues. This combined method, with the Kingery method and many others, provides such an inflammatory reaction, which aids in the cure.

The urine should be regularly examined for albumin and casts when mercurials are used. Daily shampooing is an important part of any of these treatments. Careful inspection of the scalp, with microscopic examination of the hair in caustic potash solution, and cultures from the hair should be kept up for many months after clinical cure.

If roentgen or thallium acetate treatment is necessary, an interval of rest should be given that all inflammatory reaction may subside before the more severe treatment is begun.

ARTHRITIS WITH BURNING SENSATION IN LIMBS

To the Editor:—A man, aged 70, has been troubled for two and a half years with arthritis involving the elbows, wrist, hands, knees and ankles. He is undernourished and has a moderate secondary anemia and considerable generalized atherosclerosis. The joints show hypertrophic changes, with some limitation of motion in the upper extremities. Under foreign protein, iodide and salicylate medications, the joints have shown some improvement, but for the past month the patient has suffered considerably with a marked burning sensation in the lower extremities, from the knee down, coming on generally at night. The burning is not noticeable when the patient is sitting up or walking about. Amidopyrine, acetylsalicylic acid, and codeine and anytal compound have been tried, also various local applications without effect in relieving the burning sensation, which now is interfering with the patient's sleep. Could you suggest any medication or method of treatment that will relieve the patient from this distressing symptom? The pulsation in the dorsalis pedis is present. The extremities do not show any objective temperature changes and there is no cyanosis when in dependent position. Please omit name.

M.D., Tennessee.

ANSWER:—The symptoms may not be due to true arthritis but to a related or superimposed condition. One thinks of circulatory disturbances of the lower extremities, such as those due to arteriosclerosis, thrombo-angiitis obliterans, acroparesthesia and various vasomotor circulatory neuroses.

Measures that may be of value should include:

1. Physical therapy to the upper extremities; cold applications and contrast applications; that is, warm and cold applied alternately to the lower extremities.
2. Improving the condition of the blood.
3. Posture exercises; that is, so-called Buerger exercises.
4. Operation on the sympathetic nervous system, which should be considered after the Brown test indicates the anticipated value of this procedure.
5. Vaccine, which may be tried without any promise.

PELVIC PAIN DURING COITUS

To the Editor:—I have a woman patient, aged 32, who is normal in all ways except for a slight constipation. She has been married for about eleven years and has one child 10 years of age. This labor was preceded by a severe period of vomiting. She has had two severe attacks of gall-bladder disease but has had no operations except tonsillectomy and hemorrhoidectomy and no other sicknesses. Her physical examination is entirely negative. She enjoys coitus and experiences a strong orgasm. There is no discomfort at all during the process of coitus or the accompanying orgasm. For the last three or four months the orgasm has been particularly marked in severity and for the last two months she has experienced a pain which is sharp and spasmodic in type, occurring about ten minutes after the orgasm and lasting for about ten minutes. It is accompanied by a slight nausea and is relieved by light massage, at which time there seems to be some slight shifting of gas in the bowel. There is no pain unless there is an orgasm. Prior to two months ago there was no pain at all. The pain is located deep in the pelvis on one side or the other or both. Can you suggest the cause of the pain and any treatment of the symptoms? Please omit name.

M.D., Oregon.

ANSWER:—Cases of this condition, which is allied to dyspareunia, have been described in the literature, although the condition is far from common. They are generally psychic in character, and psychic treatment is in order. A case in point is one in which a young girl had been raped and the act was accompanied by severe abdominal pain. Years later, when she

married, each act of coitus was accompanied or followed by such abdominal pain. In other cases the act of coitus, while perfectly normal and pleasurable, is followed by headache, nausea, vomiting, diarrhea and vertigo.

The most important point in treating these cases is to find some local pathologic condition which might be the cause of these disagreeable sensations. Although the history given states that the physical examination is normal, it must be remembered that at times apparently minute and unimportant lesions may exist which may be the source of these symptoms, such as a minute anal fissure or areas of hyperesthesia either in the genital organs or about the anus. Should none of these conditions be discovered, the case must be considered purely psychic and it may be necessary to have a psychoanalytic examination to determine the cause of the trouble.

ORTHOPEDIC SURGEONS ABROAD

To the Editor:—Can you give me a list of noted orthopedic surgeons in Europe who are particularly noted for doing something out of the usual routine of orthopedic work? For example, Lange in Germany, noted particularly for his silk strand tendon surgery; Schmorl, noted for his research in intervertebral disk injuries, and Böhler of Vienna. I will appreciate any information you may give me concerning this.

HERBERT E. HIPPS, M.D., Dallas, Texas.

ANSWER:—The prospective traveler will find that in almost every large orthopedic clinic in Europe either the chief of the clinic or some of his assistants speak English. There are also other English speaking visitors who will aid the person not familiar with the language in understanding significant statements made by the teacher. A list of important orthopedic surgeons abroad follows:

* Sir Robert Jones died on or about January 14.

HYPERSECRETION DURING PREGNANCY

To the Editor:—Can you give me the best treatment for a primipara, aged 25, finishing three months of pregnancy, who is of a nervous type and of slender build with alternating nausea and vomiting and abundant hypersecretion, wetting four or five bath towels a day? Hypersecretion is bad now. Physical examination gives normal results. The secretion just tires her out. I have prescribed complete rest in bed for a month, with no visitors, a dry diet, alkali powders and allonal tablets. Please omit name.

M.D., Minnesota.

ANSWER:—Generally there is a diminished functioning of the sweat glands during pregnancy. This diminution becomes intensified as gestation progresses but during the puerperium there is a sharp reversal, so that severe perspiration is fairly common during the first few days after delivery. The greatest

decrease in the elimination of fluids through the skin during pregnancy occurs in women who have nephritis and eclampsia; hence in these women the kidneys have an extra burden to carry. However, some women exhibit an increased tendency toward sweating during pregnancy and the parts most affected are usually the abdomen, breasts, back and vulva. The patient's general resistance is lowered as a result of this drain of fluid. The cause of the excessive perspiration is undoubtedly a disturbance in the nervous mechanism. Unfortunately there is no specific remedy that will diminish the activity of the sweat glands and the most one can do is to build up the patient's resistance, replace the fluid lost by the ingestion of large amounts of liquids, and administer mild sedatives such as the bromides. In addition to this it is highly important to supply the patient with abundant sodium chloride. This is in accord with the following statement, which appeared in *THE JOURNAL*, March 25, page 989:

Profuse sweating results in a loss not only of considerable volumes of water but also of surprisingly large quantities of salt. It is well known that the physiologic integrity of the neuromuscular mechanism is highly dependent on the presence of inorganic ions. . . . A rapid dilution of intravascular and interstitial fluids diminishes the osmotic pressure with the result that, until readjustment is made either by ingesting salts or by excreting the excess water, subjective symptoms occur varying from mild fatigue and lassitude to actual muscular cramps in man and convulsions and death in experimental animals. Among stokers, iron workers and miners, such cramps occur in individuals who, during severe sweating, drink large quantities of water. It has been shown that the seizures do not occur if salt solution is consumed instead of water; furthermore, appetite is maintained and a feeling of vigor and freshness after the hard day's work has been noted.

ECZEMA OF FACE DUE TO SENSITIVITY

To the Editor:—A woman, aged 54, came to my office with a case of eczema erythematousum on the right side of the face, the right eye being entirely closed from the edema, the skin roughened and slightly infiltrated. From my inquiries, this condition was brought on from eating fish three days before. Moist compresses of a solution of boric acid, resorcinol and phenol (1 per cent) relieved the condition and one week later the skin was clear, outside of the desquamation taking place. Three weeks later, the patient put on some face cream and powder, and in twenty-four hours the weeping eczema was back. The foregoing treatment was resorted to, again with good results. Six weeks after the desquamation was at an end, the patient again applied face cream and powder, and the eczema recurred in twenty-four hours, as previously. Can you suggest some kind of cream or lotion that would relieve the feeling of dryness and form a base for face powder without irritating that peculiarly sensitive skin? Kindly omit name.

M.D., New York.

ANSWER.—It is assumed from the description that the second and third attacks of dermatitis were in the same area as the first. This would signify that the skin of this area has become sensitized in some way to face powder, most likely to orris root, an ingredient of many face powders, or, what is less likely, to some ingredient of cold cream. Perhaps it is the application of a soft ointment that brings out the dermatitis. The patient should use zinc paste consisting of zinc oxide, colored with calamine powder to the proper shade, and starch, 25 per cent of each in petrolatum. This should be mixed and applied thinly. Or she may use as a powder base tragacanth lotion, tragacanth powder, 5 Gm.; boric acid, 15 Gm.; glycerin, 15 Gm.; water, to make 500 cc. The tragacanth is shaken with the glycerin and the boric acid powder; then the water is added in four parts, the mixture being shaken vigorously on each addition of water. Rose water or other perfumes may be added if one can be sure that the patient is not sensitized to them. "Allergen free" face powders are to be obtained and may be useful in this case.

EXAMINATION OF URINE OF PATIENTS IN COMA

To the Editor:—Please state whether urinalysis usually reveals casts and albumin in most cases of deep coma from disease. In a recent meeting of our county medical society, apparently, I was alone in my opinion that these abnormal constituents were usually present in most cases of deep coma. Twenty years ago, Cabot, in the second edition of his "Differential Diagnosis," mentioned their presence in the urine of most of the cases of coma due to causes listed in his table XIV. Please omit name and address.

M.D., Arkansas.

ANSWER.—Deep coma, or unconsciousness from which the patient cannot be readily aroused, may be due to a variety of disease conditions. The most important are uremia, diabetes, cerebral hemorrhage, cerebral thrombosis, cerebral embolism, brain injury, puerperal eclampsia, epilepsy, epidemic encephalitis, and meningitis.

In cases of coma, examinations of the urine, cerebrospinal fluid and blood are all important and should be done as soon as possible. Two conditions often coexist. A patient may have diabetes and develop a cerebral hemorrhage or thrombosis. A man may develop uremia while he is drunk. A head injury

may result from a fall due to coma. A complete and thorough examination of the patient is always desirable, even though an apparent cause has been found.

A urine examination should be made in every case of coma. This urine examination alone is never sufficient to establish the diagnosis, as albumin and casts may be due to various poisons, passive congestion or renal disease. Uremic or diabetic coma is unlikely if the urine is normal.

Casts are present in the urine in most kidney diseases, being numerous in the acute and chronic forms, especially with edema. They are less frequent in the primary contracted kidney or arteriosclerotic kidney usually found in essential hypertension. They also occur in the urine in chronic passive congestion, febrile albuminuria and marked jaundice. In diabetic acidosis with coma, granular casts are often found. In fact, casts may occur in any condition in which the kidneys are altered by toxic, inflammatory or circulatory disturbances.

Hyaline casts may be found in small numbers even in normal urine after sufficient search. They are not pathognomonic of any one condition. When numerous, they indicate a renal disturbance. In the marked pathologic changes of acute, sub-acute or chronic nephritis, other types of casts (granular, epithelial, waxy, blood casts, pus casts) are also found.

TOXICITY OF LACQUER THINNER

To the Editor:—Will you please tell me if there is any toxic effect from breathing the fumes of or working with the lacquer thinner made by the Jones Dalbey Company of Detroit? Any information regarding this product will be greatly appreciated.

RONALD F. GARVEY, M.D., Olean, N. Y.

ANSWER.—The lacquer diluents made by the firm mentioned are believed to be similar to those in wide use throughout the country. These diluents may contain toluene, butanol and butyl acetate, among other constituents. Benzene is a common ingredient, but the firm mentioned states that benzene is not used. Other constituents in some, but not all, diluents are amyl, methyl and ethyl alcohol, naphtha and xylene.

In the absence of benzene and methyl alcohol, toluene is the most probable source of serious damage to exposed workers. Toluene may be more toxic than benzene in the production of acute manifestations but is less liable to induce the chronic state characterized by leukopenia, hemorrhage, anemia, and general increased susceptibility to infection—the well known clinical picture of benzene poisoning. However, both toluene and xylene are capable of causing such manifestations. The clinical state is not distinguishable from benzene poisoning. Various other constituents of lacquer diluents may produce inflammation of the respiratory tract and skin. Various chronic conditions may be caused by naphtha, but as yet these lack proper descriptions beyond the assertion that manifestations resembling those of multiple sclerosis may arise. Industrial methyl alcohol poisoning, including blindness, is possible, but at this time industrial methyl alcohol poisoning is rare.

NODULES IN BREAST

To the Editor:—For a period of five years I have observed a patient who has several small nodules in each breast. These increase in number before each menstrual period and many of them disappear after the menstrual period. The nodules are about 1 cm. in diameter, appear to be in the gland tissue, and are freely movable and somewhat painful on pressure. Will you kindly let me know what the nature of these nodules may be and whether there is a possibility that they may become malignant? Please omit name.

M.D., New York.

ANSWER.—There are three possible lesions to be considered; in the order of probability they are (1) mazoplasia, (2) multiple fibro-adenomas and (3) multiple cysts. The age of the patient would help in the differential diagnosis. Mazoplasia, or what is erroneously called chronic mastitis, is the most likely probability, especially if the nodules vary in size with the menstrual period. All the available evidence indicates that this state is not a precursor of cancer. Multiple fibro-adenomas are a possibility, especially if the lesion dates back to the time of puberty. Transillumination of the breasts might help to differentiate the state from multiple clear fluid cysts. If the lesions are fibro-adenomas, they bear no relation whatever to cancer and then the possibility of a malignant change is practically eliminated. The third possibility is that the mass represents small cysts. In this circumstance there is some danger of a superimposed malignant change. The bilateral nature of the lesion is in favor of a benign process. Age is of some importance: the younger the patient, the less chance of a malignant condition. The danger signal is localization. Localized nodularity in one breast is an indication for immediate surgical exploration and microscopic examination.

EFFECTS OF LOCAL ANESTHETIC APPLIED TO EAR DRUM FOR SEASICKNESS

To the Editor:—In two recent issues of *Time* (January 16 and February 27, pp. 2 and 5) there are accounts of a treatment for seasickness applied by Major Coupal, physician to the late ex-President Coolidge. The treatment consisted of placing pledgets of cotton soaked in a solution of tutocaine or psicaine, or other non-habit forming derivative of cocaine in the ears. I am at present engaged in marine bacteriologic work which necessitates trips at sea in a small boat for periods of a few days to a week. Being susceptible to seasickness, I sometimes find my work interfered with by this unpleasantness. Can you give me any information as to the concentration in which these drugs are used and their efficacy in controlling seasickness? Will their use result in any impairment of the sense of balance? Are there any precautions to be preserved in their use? If you do not have this information at hand, perhaps you can refer me to some physician who has had actual experience with this treatment.

HERBERT W. REUSZER, New Brunswick, N. J.

To the Editor:—Is there any evidence that a local anesthetic applied to the ear drum can have an effect in seasickness? A patient sent me the clipping enclosed, which appears to involve the usual amount of journalistic misinformation. I shall be grateful to have some authoritative comment on this point. If published, please omit my name.

M.D., New York

ANSWER.—It is doubtful whether tutocaine or psicaine applied on a pledget of cotton and inserted into the ear canal would be sufficiently absorbed to have any systemic effect, as the lining of the drum head is of epidermal nature. It is quite probable that the effect was entirely psychic and due to suggestion. Even if the medicament could be absorbed by application to the drum head, there is no likelihood that it could affect the semicircular canals, disturbance of which is the cause of seasickness, as the relations of the blood supply would make a direct transference from the outer ear to the inner ear an anatomic impossibility.

No substance such as tutocaine, cocaine or psicaine, or other anesthetic, is capable of penetrating the unbroken skin. Even if there were a perforation in the drum membrane, so that the anesthetic solution could of course enter the middle ear, it has never been demonstrated that the solution would then have a definite effect on the semicircular canals.

USE OF GLANDULAR EXTRACTS TO INCREASE GROWTH

To the Editor:—Would you please advise me regarding the possibility of any of the glandular extracts increasing the growth of a man, aged 22. He is 4 feet 11 inches (150 cm.) tall, well built, normal in development, normal in sexual development, and, in fact, just a small individual. Physical examination is negative, other than a slow pulse (never above 68 when at rest). Mental examination shows an individual above the average in mentality, always good in school work, and with good business ability. He has had no serious illness, but at 11 years of age he had severe occipital headaches, not helped by glasses, but apparently relieved by the extraction of a molar tooth. An uncle was small until he was 22 years old, when he started to grow and was 5 feet 8 inches (173 cm.) tall at 28 years. The father was 5 feet 3 inches (160 cm.) tall; the mother about 5 feet 4 inches (162.6 cm.); one sister 5 feet 5 inches (165 cm.) at 12 years; one brother 5 feet 6 inches (167.6 cm.) at 16 years. The patient weighed 12 pounds (5.4 Kg.) at birth and was breast fed. His growth was apparently normal until he was 12 years old and he has not grown since. I advised him that there was little to be done, but that I would get some advice. Please omit name.

M.D., Nebraska

ANSWER.—The discussions of dwarfism occurring in the literature contain much on nosology but little on pathogenesis.

Undergrowth, or dwarfism, as applied to the individual referred to in the query, indicates a defect in growth only. Dwarfism due to defective development is spoken of as infantilism. The individual under consideration undoubtedly belongs to the group spoken of as true dwarfs.

Hanseman described a primordial and an infantile type of true dwarfism. In the latter type the individual is of normal size at birth. Growth continues for a certain period and ceases sometime between early childhood and puberty. Paltauf, about 1891, called attention to the primordial type of true dwarfism, and described such a skeleton, of an individual who died at 49 years of age, whose epiphyses had not yet completed their development. The dwarf was 45 inches (114 cm.) in height, normally intelligent, had good heredity, and the thyroid gland was normal. It has been maintained that this type of dwarf may begin to grow in adult life. Thus it is recorded by Paltauf that two increased in height as late as their thirtieth year. This may be explained by the persistence of the immature type development of the epiphyses.

In most of the cases described belonging to the primordial, or Paltauf, type the intelligence remains normal. The etiology is obscure, while the retarded development of the epiphyses may in some way be associated with the failure to grow. Nevertheless, what causes the delay in the development of the epiphyses?

True dwarfism does not seem to depend in any demonstrable way on endocrine dysfunction. All studies have failed to show involvement of either the hypophyseal or the thyroid gland.

EXERCISES FOR SPASTIC PARALYSIS DUE TO CEREBRAL HEMORRHAGE IN CHILD

To the Editor:—Please recommend appropriate exercises for a boy, aged 4½ years, with a residual spastic paralysis of both legs and the right arm, following hemorrhagic cerebral injury at birth. The gait is spastic with relatively little tendency to scissoring. The feet are inverted and rotated in. The heels come down well and there is no flexion deformity of the knees. Sphincter control is good. What may be expected of a Stöffel operation in this case and what would be the optimal age? Would this operation eliminate the remains of the scissoring?

J. E. REEVES, M.D., Norfolk, Va.

ANSWER.—Appropriate exercises must be outlined to fulfil the requirements of the individual case. A standardized group of exercises cannot be applied to spastic paralysis. It is necessary to examine the muscular action of each joint in order to ascertain the strong or dominant groups from their antagonists. The exercises are then outlined to increase the power of the antagonists and thereby lessen the power of the deforming groups.

Exercises should consist of individual muscle contractions and group muscle contractions both in and out of water. For the types of exercises applicable to the various joints and for a method of muscle examination, the correspondent is referred to the chapter on Muscle Training in Jones and Lovett's Textbook of Orthopaedic Surgery, New York, William Wood & Co. In a monograph by Dr. Loyal Davis in volume 2 of the Principles and Practice of Physical Therapy, published by Prior and Company, the following references are given:

Franz, S. I.; Sheetz, Mildred E., and Wilson, Anita A.: The Possibility of Recovery of Motor Function in Long-Standing Hemiplegia, *THE JOURNAL*, Dec. 18, 1915, p. 2150.

Crothers, Bronson: Birth Injuries of the Central Nervous System, in *Medicine Monographs*, volume 2, Baltimore, Williams and Wilkins Company 1927.

Frankel, H. S.: The Treatment of Tabetic Ataxia by Means of Systematic Exercise, English edition translated and edited by L. Freyberger, Philadelphia, 1902.

The most important phase of spastic therapy is exercises. If contractures or deformities are present, the exercises will be of no avail because of these hurdles. It will be necessary to correct these contractures and deformities to permit proper exercising. The Stöffel operation is one of the means of overcoming these obstacles.

The most suitable age is 5 or 6 years, because the child will be old enough to cooperate in the performance of the exercises, which cooperation is so valuable as a postoperative measure. The Stöffel operation will eliminate the remains of scissoring only if the scissoring is caused by spasticity of the adductor muscles of the hips. If it is caused by contracture of these muscles, it will be necessary to do myotomies at the same time.

STERILIZATION OF CATGUT ENDS

To the Editor:—Is there any way to sterilize satisfactorily ends of catgut saved from one operation for future operations? Please omit name and address.

M.D., India.

ANSWER.—Catgut ends may be sterilized, after rinsing in water, by immersing them in 95 per cent alcohol for from two to five days. If desired, a few drops of iodine may be added to the solution. Such pieces may then be used safely for ligatures and sutures preferably in operations close to the surface, such as repair of lacerations, perineorrhaphies and hemorrhoids instead of intra-abdominally, because the washing in water and the use of alcohol may reduce the tensile strength of the catgut.

USE OF IODINE POWDER IN NOSE

To the Editor:—I wish to use 4 per cent iodine in a powder combination to be carried by hot air into the antrum. How much iodine could one use with safety, provided the patient has been previously tested on potassium iodide to determine the absence of an idiosyncrasy? Please omit name.

M.D., Washington.

ANSWER.—Iodine is both a powerful germicide and a marked irritant to the mucous membrane of many persons. It is perhaps advisable, therefore, to use the iodine powder in combination with boric acid in concentrations of 1 or, at the most, 1.5 per cent. It is difficult to say how much powder could then safely be carried into the antrum. Only a small amount should at first be used until the tolerance of the patient can be well established.

EXAMINATION OF FUNDUS OF EYE

To the Editor:—What is the best equipment now available for examination of the fundus of the eye in red-free light? This would preferably be as compact and as inexpensive as possible. Please omit name and address.

M.D., Minnesota.

ANSWER.—The words "compact" and "inexpensive" must be forgotten in the discussion of examination of the fundus of the eye in red-free light. The instrument of greatest availability is the Friedenwald ophthalmoscope with its glass filter. For the average clinical examination, this is perfectly satisfactory, but for careful study of the yellow macula the light is not as red free as might be desired. Somewhat more cumbersome is the ordinary arc lamp, such as is used for dark field microscopic studies, armed with a red-free filter. This may be either a Wratten filter (made by the Eastman Kodak Company) or a glass cell with the well known cobalt blue solution. The arc lamp must have a condensing system so that the emergent beam consists of practically parallel rays, which are then reflected into the eye by the ordinary reflecting ophthalmoscope. The self-luminous ophthalmoscopes with red-free filters are, with the exception of the Friedenwald, entirely inadequate.

DRIED SERUM IN BLOOD TESTING

To the Editor:—I shall be greatly obliged if you will inform me of the advantages and disadvantages of the use of dry standard serum for blood grouping. Please advise me in which cases it is better to use the dry standard serum. I shall greatly appreciate receiving this information, also titles and authors of any literature, American or European, on the subject. Please omit name and address.

M.D., New York.

ANSWER.—There are no advantages in using dried test serum for blood grouping. In addition to the necessity of making proper solution of the dried serum comes the fact that it may have undergone deterioration. There are no cases in which it would be better to use dried serum on account of the nature of the case. The subject of blood grouping is considered thoroughly from all points of view in the following books:

Snyder, Laurence H.: Blood Grouping in Relation to Clinical and Legal Medicine, Baltimore, Williams & Wilkins Company, 1929.

Lattes, Leon: Individuality of the Blood in Biology and in Clinical and Forensic Medicine, translated by L. W. Howard Bertie, New York, Oxford University Press, 1932.

Steffan, Paul: Handbuch der Blutgruppenkunde, Munich, J. F. Lehmanns Verlag, 1932.

"ALBUMINURIA IN YOUNG ADULT"

To the Editor:—In Queries and Minor Notes (THE JOURNAL, April 29), treatment was outlined for albuminuria in a young adult. When there are no casts in an albumin-free morning specimen I have been advising generous protein diet with apparent benefit. In one case, casts in the day urine disappeared but this may have also been due to previous removal of the focus. Please advise whether you have anything on high albumin intake in these cases. Please omit name.

M.D., Washington.

ANSWER.—When by repeated urine and physical examinations the diagnosis of orthostatic albuminuria can be made with reasonable certainty, no restriction in diet is necessary or desirable. If, on the other hand, a presumptive diagnosis of nephritis is made, the usual practice is to limit or prohibit a protein diet. It is true that in nephroses many clinicians give the so-called Epstein diet, which is high in protein substance. It is also true that in some clinics higher protein diets than have been customarily sanctioned by general usage have been tried in cases of chronic nephritis. The results of this newer dietary treatment of chronic nephritis are not known and should be considered to be in the experimental stage.

EPILEPSY IN ADOLESCENCE

To the Editor:—A girl, aged 14, has been menstruating regularly for the past six months. Over the same period there have been progressive epileptic seizures beginning first as the jacksonian type but now generalized, with loss of consciousness. The child has been growing rapidly, she is tall and ungainly, and the facies is rather dull, with a nervous, foolish, embarrassed expression. The previous history was good, with normal advancement in school, no positive history in the family, and no trauma. Please give the probable cause for these seizures and outline the treatment.

M.D., Texas.

ANSWER.—The data given would lead one to think that the attacks are of the usual epileptic type and that the patient may come to have ordinary epilepsy. However, it is not uncommon for such attacks to last several months or a year or two and then cease. The treatment ought to be the same as for a case of full-fledged epilepsy. At least 0.1 Gm. (1½ grains) of phenobarbital should be given daily and the easiest way is to give it at a single dose in the evening.

Council on Medical Education
and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD FOR OPHTHALMIC EXAMINATIONS: Boston, Sept. 19. Application should be filed before August 1. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

CALIFORNIA: Regular. Los Angeles, July 24-27. Reciprocity. Los Angeles, July 24. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: Endorsement. Hartford, July 25. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. The examinations will be held at centers where there are five or more candidates, Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SOUTH DAKOTA: Watertown, July 18. Dir., Dr. P. B. Jenkins, Pierre.

WASHINGTON: Basic Science. Seattle, July 13-14. Regular. Seattle, July 17-18. Dir., Mr. Harry C. Huse, Department of Licenses, Olympia.

Tennessee March Report

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held in Memphis, March 23-24, 1933. The examination covered 8 subjects. An average of 75 per cent was required to pass. Twenty-eight candidates were examined, all of whom passed. Three candidates were licensed by endorsement and one by special exemption. The following colleges were represented:

| College | PASSED | Year Grad. | Per Cent |
|--|--------|------------|----------|
| Georgetown University School of Medicine..... | (1929) | | 81.4 |
| Tulane University of Louisiana School of Medicine..... | (1932) | | 89.8 |

Book Notices

Fungous Diseases: A Clinico-Mycological Text. By Harry P. Jacobson, M.D., Attending Dermatologist and Member of the Malignancy Board, Los Angeles County General Hospital. With Introduction by Jay Frank Schamberg, M.D., Professor of Dermatology and Syphilology, Graduate School of Medicine, University of Pennsylvania, and Howard Morrow, M.D., Clinical Professor of Dermatology, University of California Medical School. Cloth. Price, \$3.50. Pp. 317, with 153 illustrations. Springfield, Ill., and Baltimore: Charles C. Thomas, 1932.

Any author would be fortunate in having either one of the flattering introductions written by such distinguished men as Dr. Schamberg and Dr. Morrow, but to have two such introductions in his volume is honor indeed. Reviewing the great developments in medicine due to such giant intellects as those of Pasteur, Lister, Koch, Roentgen, Ehrlich, the Curies, Dean and Wrenshaw, Dr. Morrow, in bringing the progress of medicine down to date, says: "This is what Dr. Jacobson has done in his treatise on Mycology. It comes to the medical world as a new departure in an hitherto uninvestigated branch of medicine. Most books on dermatology written in Europe treat the subject lightly; few books in America treat of the subject at all." One wonders what is meant by the statement that the book "comes to the medical world as a new departure in an hitherto uninvestigated branch of medicine." Such a statement not only invites but demands comparisons. "Les teignes," which was published by Sabouraud in 1910, and which is still the Bible of mycology, is now out of print. "Dermatomykosen" (volume 11 of the Handbuch der Haut- und Geschlechtskrankheiten) was published in 1928. One has only to glance through the latter book to be impressed by the enormous amount of investigative work that has already been done in mycology. The statement that "few books in America treat the subject at all" is surprising in view of the fact that Ormsby in "Diseases of the Skin" (1927) devotes eighty-three pages to the mycoses, which is almost a third as much material as is in Jacobson's whole book. Andrews in "Diseases of the Skin" (1930) devotes fifty-eight pages to the subject.

To quote Dr. Morrow in one more sentence, "Adding to his art of observation and his years of skilful practice his power of accurate recording, Dr. Jacobson, the successful physician, is now welcomed as the authentic author." What is meant by authentic author? Does it mean "of approved authority"? Despite the thoroughness of the bibliographic work in "Dermatomykosen," the only reference one finds to the author's work is to an article on granuloma coccidioides. Of the illustrations, about sixty-five are the author's, of which about fifty are on deep mycoses only. About eighty illustrations have been lent by American workers, and six by German publishers. Practically all of these eighty-six illustrations are in the dermatomycoses chapters. If a medical student were so unfortunate as to have one of the American textbooks, whatever that one may be, which does not treat of the mycoses, and were obliged to depend on this volume, he would remain in ignorance of such vital subjects as trichophytids, microsporids, dermatophytids and trichophytin. And if he were to become interested in the work of Americans he would find no mention of Charles Mallory Williams, none of Hodges, Lane, Wende or Sulzberger, and only one reference to Weidman. If interested in foreign workers he would find no mention of Priestley, only one reference to Kaufmann-Wolf, spelled in the index Kaufman, and only one to Jadassohn, spelled in the index Jadessohn.

If the medical student wanted to read up on the technic of epilation, to which Andrews devotes thirteen and one-half pages, he would be enlightened as follows:

The accepted method of therapy of ringworm of the beard is a combination of x-rays to the lesions and thallium acetate by mouth. The technique of the treatment consists of ascertaining the patient's weight (nude), and then, administering by mouth thallium acetate (3 mg. per kilo of body weight) in one dose and on an empty stomach. This is followed, the same day, by roentgenotherapy.

The primary purpose of this combined method of treatment is to cause complete epilation of the affected hair without the risk of producing cutaneous atrophy. Without the oral administration of thallium acetate, the required x-ray dosage for epilating purposes is much greater and therefore more risky from the standpoint of the possibility of an ensuing radiodermatitis with resulting atrophy.

When the involvement is limited to a single patch, the following factors are usually employed: 9 inch spark gap (137 K. V.) 5 mamp., 3 mm. al. filter, 10 inches distance, 6 minutes time. When the infection is more widespread and there are several areas to be rayed, with the consequent possibility of overlapping, the time element should be reduced to about 5½ minutes for each area treated. Epilation usually takes place seven days after treatment.

All cases of tinea capitis of limited involvement or with extensive involvement, but approaching the age of puberty (12 to 15 years old), should be treated by conservative methods of local medicinal applications in accordance with any of the above outlined schemes. Young patients with extensive involvement and all types and degrees of favus of the scalp should receive the benefit of epilating doses of x-ray (Kienböck-Adamson method), with or without thallium acetate by mouth, as described under the treatment for tinea barbae.

No mention is made that the correct dose of thallium acetate epilation without roentgen rays is 8 mg. per kilogram of body weight. The upper age limit of safety for thallium acetate is now looked on as nearer 10 years than 15. No attempt is made to describe the exceedingly difficult Kienböck-Adamson technic.

For the treatment of onychomycoses the medical student would read on page 72 that "bathing the parts for thirty minutes at night and morning in merthiolate solution (1:3) have produced satisfactory results in two patients with onychomycoses."

The book is well printed on good paper. The illustrations for the most part are excellent. The proof reading, especially of the index, as the examples quoted show, is poor. The chapters on the deep mycoses are excellent. The author speaks with authority on granuloma coccidioides, but the reader gets the impression that the chapters on the dermatomycoses were written with a less sure hand.

Die Behaarung des Menschen: Eine sexual- und konstitutionswissenschaftliche Abhandlung. Von Dr. Oskar F. Scheuer, Hautarzt, Facharzt für Sexualstörungen und Geschlechtsleiden. Nr. 17, Monographien zur Frauenkunde und Konstitutionsforschung. Fortsetzung der Monographien zur Frauenkunde und Eugenik, Sexualbiologie und Vererbungslehre. Herausgegeben von Dr. Max Hirsch. Paper, Price, 6 marks. Pp. 93, with 17 illustrations. Leipzig: Curt Kabitzsch, 1933.

More and more, German investigators are concerning themselves with the constitution of man in relationship to sex, disease, inheritance and similar factors. The present monograph is concerned entirely with the subject of hair, its distribution about the body in various races, the growth of dog-faced boys and bearded women, the physiology of hair growth, the growth of customs and psychologic attitudes, the effects of various disorders of the glands of internal secretion, and many similar topics. Attention is also paid to depilation, hair fetishism and magic. A bibliography supplements the monograph.

Criteria for the Classification and Diagnosis of Heart Disease. By the Criteria Committee of the Heart Committee of the New York Tuberculosis and Health Association, Inc.: Joseph H. Bainton, M.D., Robert L. Levy, M.D., Arthur C. DeGraft, M.D., and Harold E. B. Pardec, M.D., Chairman. Approved by the American Heart Association. Third edition. Cloth. Price, \$1. Pp. 131, with illustrations. New York: New York Tuberculosis and Health Association, 1932.

This work is an elaboration of the pamphlets issued from the same source dealing with radiologic and electrocardiographic diagnosis. The latter subjects are included in the present work as an appendix. The remainder of the book is devoted to developing a nomenclature for cardiac diagnosis. The criteria for diagnosis in each division are set forth following a discussion of that particular division. The etiologic diagnosis is considered under fifteen headings. The anatomic diagnosis is divided into four main headings and forty-seven subdivisions. The physiologic diagnosis is discussed in twenty-one divisions with nineteen subdivisions. Changes in the electrocardiogram also are considered here. The functional capacity of the damaged is discussed as well as possible heart disease

and potential heart disease. The discussion is short, terse, and generally acceptable. A few statements will not go unchallenged. Not all will agree that cardiac enlargement will result from thyroid disease, nor will every one subscribe to the unqualified statement that auricular fibrillation and flutter are the result of a circus movement. Generally speaking, however, the adoption of such a uniform nomenclature would greatly simplify the interchange of ideas in cardiac diagnosis.

The Rise of Preventive Medicine. By Sir George Newman, K.C.B., M.D., F.R.C.P., Chief Medical Officer of the Ministry of Health. University of London, Heath Clark Lectures, 1931, Delivered at the London School of Hygiene and Tropical Medicine. Cloth. Price, \$3. Pp. 270, with 8 illustrations. New York & London: Oxford University Press, 1932.

It is impossible to separate the rise of preventive medicine from the history of medicine generally. Most of our knowledge of public health has been derived from scientific medicine, although knowledge essential to public health work has come also from many related fields. Thus the history of the rise of preventive medicine, presented by Sir George Newman in the University of London Heath Clark Lectures, is a reflection of medical history generally. It begins with a discussion of folk lore, magic, custom and religion, considers next the rise of hygienic practices of the Egyptians and the ancient Hebrews, then the transition to Greece, the period of the Middle Ages, the Renaissance, the rise of anatomy, physiology, pathology and bacteriology, and finally the application of these discoveries to preventive practices. The ten chapters of the book therefore constitute ten significant lectures surveying the entire field of medicine. The book is written in an easily readable style and is beautifully illustrated with some fine plates. There is one aspect of the subject that is not thoroughly elucidated in this work. It is the contribution of American organizational methods to standardization and practice of preventive medicine on a large scale, the type of effort carried on by the International Health Board of the Rockefeller Foundation. Moreover, the only reference to the magnificent work of the Walter Reed Commission and to Gorgas's contribution is the single sentence "The stamping out of yellow fever on the Panama isthmus by Surgeon General Gorgas is one of its [preventive medicine's] triumphs." Notwithstanding any omissions, which perhaps the preparation of this book in lecture form made necessary, it is an inspiring and worth-while contribution to its field.

A Critique of Sublimation in Males: A Study of Forty Superior Single Men. By W. S. Taylor. Genetic Psychology Monographs, Child Behavior, Animal Behavior, and Comparative Psychology. Volume XIII, No. 1. Paper. Price, \$2. Pp. 115. Worcester, Massachusetts: Clark University, 1933.

This thesis is an attempt to find out the extent to which superior men sublimate their physical desires, and in that way to contribute further to knowledge of masculine sexuality. The men selected were between the ages of 20 and 40. The questionnaire method was used in obtaining information, and checked by various other methods five years later. The book concerns particularly the attitude toward masturbation, relationships to women and the general psychology of sex. The book does not find any solution for the problem of sex in the young adult male. There are both advantages and disadvantages for any form of adjustment. The author is inclined to believe that early marriage is the best way, but there seem to be plenty of disadvantages associated with that. It is evidently the best way from the sexual point of view but neglects other important factors. The author is inclined to recommend early marriage according to Judge Lindsey's formula, with legalized birth control and the right to divorce by mutual consent for childless couples without payment of alimony.

The Medical Annual: A Year Book of Treatment and Practitioner's Index. Edited by Carey F. Coombs, M.D., F.R.C.P., and A. Hendle Short, M.D., B.Sc., F.R.C.P. Fifty-fifth Year, 1932. Cloth. Price, \$6; 20/- Pp. 674, with 260 illustrations. Baltimore: Williams & Wilkins Company; Bristol: John Wright & Sons, Ltd., 1932.

The Medical Annual begins with a review of its past, including a great series of portraits of present and past contributors. The remainder of the book is essentially a dictionary of medicine prepared by many writers, who call attention to recently published articles. In the introduction, the authors point with pride to new material on the use of inhalations of carbon dioxide, new studies of the blood, the use of cortin in Addi-

son's disease, and changes in the methods of treating meningitis, scarlet fever and dysentery. In their comparison of various hypnotics they insist that chloral hydrate and barbital are the cheapest and best of the nonalkaloidal hypnotics and they recommend smaller doses than are ordinarily used; namely, $2\frac{1}{2}$ grains (0.16 Gm.). Attention is also paid to new points of view in gynecology, one of the points being that cresol as an antiseptic is better replaced by brilliant green in obstetric antisepsis. The authors seem to believe that the injections of lead selenide in inoperable cancer are useful. Certainly, a review of the volume indicates that the contributors are not chosen because of therapeutic nihilism. Exceedingly valuable are a series of supplements dealing with new pharmaceutical preparations, new appliances, a list of books published during the year, a list of the mental institutions in Great Britain and a directory of trades.

Behavior Mechanisms in Monkeys. By Heinrich Klüver. Behavior Research Fund and Institute for Juvenile Research. With an introduction by K. S. Lashley. Cloth. Price, \$4. Pp. 337, with 52 illustrations. Chicago: University of Chicago Press, 1933.

In his introduction to this volume, K. S. Lashley points out that the most immediate value of such an investigation is to lay a foundation for further studies of the neurophysiology of behavior. Experimental neurology, he says, has made little progress toward an understanding of the mechanisms of thinking for lack of an adequate knowledge of the normal behavior of the animals studied. Apparently the basic investigations of the behavior of monkeys have opened the way to a more fundamental attack on the disturbances of human thinking. It is learned from such studies that there are certain patterns of response which are not affected by changes in environment, that actions depend on one another and that there are mechanisms rather than single stimuli which determine the responses of both animals and men to various situations.

Medicine and the State: The Relation Between the Private and Official Practice of Medicine With Special Reference to Public Health. By Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P. With foreword by William H. Welch, M.D., LL.D. Cloth. Price, \$3.50. Pp. 300. Baltimore: Williams & Wilkins Company; London: George Allen & Unwin, Ltd., 1932.

In its propaganda on behalf of state medicine, the Milbank Memorial Fund has been utilizing Sir Arthur Newsholme for travels, publicity and publications. The present volume is part of a series on Medicine and the State developed under these auspices. The book is, in general, a brief against private practice. The thesis of the book is that sickness insurance supported jointly by employers, employees and the state is necessary for satisfactory medical care of populations. The author endorses heartily an insurance scheme supported by employers and employees but to a certain extent by the state and under the supervision of the state. He also supports particularly compulsory rather than voluntary health insurance.

Précis de chimie physiologique. Par Maurice Arthus, correspondant national de l'Académie de médecine de Paris, et André Arthus, privat-docent de physiologie à l'Université de Lausanne. Eleventh edition. Cloth. Price, 65 francs. Pp. 322, with 116 illustrations. Paris: Masson & Cie, 1932.

When the first edition of this work was published, in 1895, it filled a gap between the fields of physiologic chemistry, strictly speaking, and medicine, particularly physiology. The physician of that day received little enlightenment from his contemporary textbooks on physiologic chemistry, which were busily engaged in classifying discoveries in pure chemistry. He learned little from the tracts on physiology, which included at best a chapter or two in recognition of the chemical application to bodily processes. In this dilemma, Dr. Arthus decided to summarize the chemical facts of physiology in health and disease. The present is the eleventh edition of a summary representing the elementary and essential facts of physiologic chemistry which the student of physiology must master. It has been translated into four languages. There are twenty-three chapters covering every division of such subjects as foods, ferments, body fluids and body tissues. The detail into which this unassuming epitome engages is illustrated by chapters on solutions and cryoscopy, gas metabolism, milk, hormones and antibodies. Each chapter is preceded by a brief summary of its contents, making the material unusually accessible. The work abounds in chemical formulas and illustra-

tions of the subject matter as well as typical laboratory apparatus with which the reader should become familiar. Added to the text are excellent colored plates illustrating spectroscopic pictures of blood, analysis of common foods and urinary tests. Although its author has striven to elucidate only elementary and fundamental considerations, the volume has achieved reference proportions. This work should be of inestimable value to the student and physician familiar with French for its clarity, conciseness and completeness.

The Rheumatic Infection in Childhood. By Leonard Flindlay, M.D., D.Sc., M.R.C.P., Visiting Physician, East London Hospital for Children, Shadwell. Cloth. Price, \$3.50. Pp. 187, with illustrations. New York: William Wood & Company, 1932.

This book summarizes the author's experience as physician to the Royal Hospital for Sick Children in Glasgow during the years 1914-1930. It is remarkable in that the author was able to trace 693 out of 701 children during that period. The survey covers all aspects of the subject—incidence, etiology, various of the manifestations of rheumatism, chorea, arthritis, carditis, the subcutaneous rheumatic nodule, skin, pulmonary, kidney and abdominal lesions, prognosis and treatment. It is an excellent modern presentation of the subject by a skilled experienced clinician. A number of his conclusions are interesting and stimulating: "The present day view is that it is a chronic disease with acute exacerbations and hence somewhat akin to tuberculosis. . . . In any case, whatever the conclusion to be drawn from the figures relative to England and Wales, there is absolutely no evidence that in the west of Scotland rheumatic fever and chorea are becoming any less prevalent. . . . "It has long been suggested that certain types of children are susceptible to the infection as, e. g., the red haired and blue eyed. . . . It is comparatively rare to meet with it [acute rheumatic fever] among the children of the well to do. . . . Dampness of the home did predispose to the disease. . . . Like all the manifestations of the rheumatic infection, arthritis is more frequent in girls than in boys." The author's statistics on prognosis emphasize again the seriousness of the rheumatic infection: "Of those infected during childhood, about one third escape involvement of the heart. By about ten years after the onset of the infection, distinctly more than a third of the patients will have died from the severity of the cardiac implications. One third of the cases will be more or less incapacitated. . . . The death rate from rheumatic cardiac disease reaches its maximum incidence during the age period 35-45 years." The chapter on treatment is equally authoritative. The author keeps "any example of active rheumatic mischief in bed for at least three months and longer if circumstances demand." This is a scholarly, conservative presentation of acute rheumatic fever—essentially clinical—based on a prolonged and wide experience at the bedside of the rheumatic child. It can be unqualifyingly recommended to all those interested in this still unsolved problem of childhood.

Nouveau traité de médecine. Publié sous la direction de G. H. Roger, Fernand Vidal et P. J. Teissier. Secrétaire de la rédaction: M. Garnier. Fascicule X: Pathologie de l'appareil circulatoire (cœur et vaisseaux). Tome I: Cœur (première partie). Tome II: Cœur (deuxième partie). Boards. Price, 135 francs; 115 francs. Pp. 991, with 512 illustrations; 780, with 123 illustrations. Paris: Masson & Cie, 1933.

Several authors contribute to the two volumes on disease of the heart, which constitute only a section of this comprehensive system on clinical medicine. The first volume contains exhaustive discussions on anatomy, physiology, methods of examination, angina pectoris, and the general principles of treatment. Each topic is dealt with in great detail and is amply illustrated by diagrams and by reproductions of photographs. Unfortunately, the chapter on roentgenology is illustrated by diagrammatic sketches: reproductions of actual films would have added materially to the value of this part of the book. The section on electrocardiography includes a mass of detail concerning the more fundamental aspects of this diagnostic procedure which hardly belong in a book on clinical medicine. Lutembacher, who contributed most of the material comprising the first volume, in discussing cardiac failure, adheres to the traditional French conception of right and left ventricular insufficiency. The chapters on pharmacology of cardiac drugs and on treatment in general are well written and should prove interesting

to those not familiar with the methods employed on the "continent."

The second volume opens with a discussion on pericarditis and is followed by equally well balanced presentations on endocarditis, valvular disease, myocardial abnormalities, coronary occlusion and other less common conditions. The manner in which the various subjects are presented can well serve as a model for books on internal medicine. The clinical descriptions usually begin with a striking opening statement, a method so ably employed by Osler, in which is revealed as if by a flash the accumulated experience of years at the bedside. The opening paragraph describing the symptoms of coronary thrombosis will serve as an example:

The manifestations of myocardial infarct are characterized essentially by an ensemble of very severe symptoms which begin with great brutality. The clinical picture is dominated by an overwhelming anginal pain of very long duration and by cardiovascular collapse with fall in blood pressure, hypodynamic myocardium and frequently with arrhythmia. To these are added fever which is moderate but always present, leukocytosis; a pericardial reaction which is localized but ephemeral, certain gastro-intestinal symptoms and fairly characteristic electrocardiographic changes.

The scope of the work is practically beyond the efforts of a single author. These two volumes, by several contributors, contain the virtues and drawbacks usually found in any large system of medicine. Most subjects are treated skilfully and in a manner calculated to be of practical help to the clinician. Other chapters, dealing with more theoretical aspects, are perhaps overemphasized and discussed in far too great detail for a book on clinical medicine. In spite of these few possible faults, there is sufficient excellent material to make this an unusually valuable addition to any library.

The Medical Secretary. By Minnie Generleve Morse. Cloth. Price, \$1.50. Pp. 162. New York: Macmillan Company, 1933.

This is a volume of useful suggestions for doctors' secretaries. It gives the kind of information that most people with common sense can find out for themselves. Presuming that the secretary starts from scratch, the book may be useful to her. There are so many individual preferences among doctors as to the ways in which they want their case records kept, their patients met, their bills sent, their literary research developed, and even their manuscripts prepared, that it will take a clever secretary to adapt what she finds out in this book to the uses of her employer. The information is on no subject complete or even authoritative.

Le pèlerinage de la Mecque au point de vue religieux, social et sanitaire. Par le Docteur Duguet, Inspecteur général du conseil sanitaire, maritime et quarantenaire d'Égypte. Avec une préface de Justin Godart. Paper. Price, 30 francs. Pp. 337, with illustrations. Paris: Les Éditions Rieder, 1932.

Duguet presents an interesting book dealing with the pilgrimage to Mekka from the religious and social as well as the sanitary points of view. The first part, covering 117 pages, deals with the origin of the pilgrimages, their general religious and social aspects, the methods of transportation and the religious ceremonies in the holy city. This section is filled with information of interest for the general reader and is written with a broad and sympathetic understanding of the religious faith of the pilgrims. The second part deals with the sanitary aspects of the pilgrimage and recites the epidemics of plague, dysentery, typhoid and especially cholera which have taken such a heavy toll of life among the pilgrims. Many official documents have been reviewed in order to present the data dealing with the twenty-seven epidemics of cholera which occurred in Hedjaz in the space of eighty-one years from 1831 to 1912, seventeen of which took place in the last fifty-two years of this period. The last twelve of these were attended by a mortality of more than 70,000 pilgrims in the holy cities alone. There are several chapters dealing with the steps taken by the various international sanitary conferences with regard to these epidemics, since they have menaced the health of a large part of the world. Thus the author presents an authoritative and comprehensive recital of the sanitary history of the pilgrimages, a review of the progress made, and a discussion of measures that are yet to be taken. The book should have an appeal not only for those interested in the public health aspects and epidemiology of medicine but for the profession as a whole.

Forty Years of Psychiatry. By William A. White, A.M., M.D., ScD. Nervous and Mental Disease Monograph Series, No. 57. Boards. Price, \$3. Pp. 154. New York & Washington: Nervous & Mental Disease Publishing Company, 1933.

The author of this autobiography has had a long and useful career in the field of psychiatry. He tells here the details of his introduction into the field, his progress in various institutions, his first association with St. Elizabeth's Hospital in Washington in 1903, and the development of psychiatry since that date. Abroad he studied with Jung, Kraepelin, von Monakow and others. He considers the development of hydrotherapeutic methods, psychoanalysis, in which he has been a distinguished leader, and the growth of the mental hygiene movement. The relationship of psychiatry to crime is given special attention. There is also a chapter on hospital administration based on his own extensive experience. It is interesting to know that the tastes of the insane in literature are practically the same as those of the general population. Dr. White does not feel that the future, at least the near future, offers any glowing possibilities in controlling the problem of the mentally defective. However, the door to this subject has been opened only within the last two decades. Particularly promising, he believes, is the more effective employment of patients in large institutions leading toward self support. A concluding chapter gives Dr. White's credo. In this connection he feels it fundamental that each individual seek out his own deficiencies before attempting to treat those of others. A profound knowledge by man of himself will have a tendency to check distorting influences and reduce them to a minimum. The book, unfortunately, lacks an index.

Les maladies de lumière et leur traitement. Par Hubert Jausson, professeur agrégé libre du Val-de-Grâce, et François Pagès. Préface du Dr Clément Simon. Paper. Price, 45 francs. Pp. 204, with 45 illustrations. Paris: Masson & Cie, 1933.

This monograph on the diseases caused by light is introduced by a description of light, the spectrum and the absorption of the different radiations under normal and pathologic conditions. The author takes up the study of sensitiveness to light and describes a large variety of illnesses caused by light. He classifies the diseases caused by light and discusses some of them as caused by different specific rays of light. He distinguishes between the red and infra-red ends of the spectrum and the violet and ultraviolet portions. The book is beautifully illustrated and because of this and the author's extensive study and experience is well worthy of translation into English and worthy of a place in the library of those who read French.

International Health Year-Book, 1930. (Volume VI). Reports (With Vital and Public Health Statistics) on the Public Health Progress of Thirty-Four Countries and Colonies in 1929. League of Nations, Health Organisation. Series of League of Nations Publications, III. Health, 1932. III. 2. Official No.: C. H. 951. Paper. Price, \$6; 24/- Pp. 1100. Boston: World Peace Foundation; Geneva: League of Nations, 1932.

These invaluable summaries of statistics are a guide to health conditions throughout the world at the time of publication. The standard tables give information concerning areas, population, sex distribution, births, death rates from various causes classified by seasons, age and sex, infant mortality, campaigns against social disease and for the protection of mothers and children, hospital statistics, health insurance funds, and so on. A considerable section of the book is devoted to the United States covering the year 1930.

Der Bandschaden des Kniegelenks. Von Dr. Karl Gebhardt, Privatdozent und Oberarzt der Sportabteilung der Chirurgischen Universitätsklinik, München (Geheimerat Lexer). Paper. Price, 4.50 marks. Pp. 59, with 21 illustrations. Leipzig: Johann Ambrosius Barth, 1933.

This small book, written from the clinic of Professor Lexer, contains anatomic consideration of the knee joint and a discussion of injuries to its ligaments. The illustrations are reproductions of photographs, line drawings and photomicrographs, and are well chosen and executed.

The Woman's Doctor. Anonymous. Cloth. Price, \$2. Pp. 307. New York: Macaulay Company, 1933.

This book is neither fish nor fowl, neither fiction nor science, neither essay nor poetry. It is just an attempt to capitalize the public's morbid interest in obstetrics, gynecology and abortions. Issued in February, the book was little noticed and has by this time been in general forgotten.

Improvised Equipment in the Home Care of the Sick. By Lyla M. Olson, R.N., General Superintendent of Nurses at the Kahler Hospitals, Rochester, Minnesota. Second edition. Cloth. Price, \$1.25. Pp. 197, with 285 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

This volume is prepared primarily for nurses. It is full of ingenious ideas, listed in alphabetical order, telling nurses how to keep patients comfortable with the kind of equipment that can be developed out of materials found around the ordinary home. A casual survey indicates that the nurse ought to take a carpenter with her for the development of some of these devices, but probably they will constitute useful methods of keeping the husband busy in case the patient is a woman. There is an interesting section dealing with the ways in which newspapers can be used to make anything from a Kelly pad to a warm seat for a bedpan. The section on restraints is interesting; also the shower bath improvised out of a wash boiler and a garden hose. The ideas in the book are fascinating if not useful. However, nurses will know that better than any medical reviewer.

The Changing Culture of an Indian Tribe. By Margaret Mead, Assistant Curator of Ethnology, American Museum of Natural History. Cloth. Price, \$4.50. Pp. 313. New York: Columbia University Press, 1932.

The author of this volume is especially well known for her previously published books in the anthropologic field, particularly those dealing with the place of women and children in the culture of savage tribes. The present volume deals with an Indian tribal community, the investigations having been made for the American Museum of Natural History. The group chosen is anonymous and is called "The Antlers," merely as a name. The tribe concerned was a Mississippi Valley tribe whose chief contact with civilization was with the Presbyterian missions in the first half of the nineteenth century. The author discusses the reservation, its economic situation, political life, religious institutions and educational situation. The remaining half of the book deals with women in the culture of the tribe, the household organization, marital situations and various maladjustments and includes case histories of twenty-five delinquent girls and women. The volume is a fine contribution to the available literature on the psychology and social-economic situations of the American Indian today.

Chapters in American Obstetrics. By Herbert Thoms, M.D., Associate Professor of Obstetrics and Gynecology, Yale University School of Medicine. Cloth. Price, \$2. Pp. 90, with 10 illustrations. Springfield, Ill.: Charles C. Thomas, 1933.

This little volume preserves the memory of great contributors to our knowledge of obstetrics. It begins with midwifery as practiced in the Colonies in the earliest days and next considers the first book on obstetrics published in this country, that of Bard. The third chapter deals with the development of the use of ergot, and following is a discussion of Dewees and the first system of obstetrics. Other chapters are devoted to the famous essay by Oliver Wendell Holmes on puerperal sepsis, the contribution of Wright dealing with cephalic version, and the use by Channing of etherization in obstetrics. The book is beautifully printed, is illustrated with fine portraits and therefore is a nice gift for any obstetrician.

Grundzüge der Kurortwissenschaft. Von Sanitätsrat Dr. S. Lachmann. Boards. Price, 5.60 marks. Pp. 133, with 2 illustrations. Leipzig: Georg Thieme, 1933.

Here is a thoroughgoing, even though small, interestingly written and yet scientific exposition of climatotherapy, with special emphasis on the therapeutic uses of mineral water resorts.

Preparation for Marriage. Edited by Kenneth M. Walker, F.R.C.S. Introduction by Logan Clendening, M.D. Cloth. Price, \$2. Pp. 175, with illustrations. New York: W. W. Norton & Company, Inc., 1933.

We are now in a well organized world, so that much of the romance of marriage is to be eliminated through complete education in advance as to all the details. This book is compiled by its editor from a number of articles by well known authorities on the subject. One can conceive a young couple working out carefully, with the aid of this volume, every step in their romantic contacts from two months before the altar to a visit to the delivery room. The psychologists, however, will be troubled as to whether or not this technocratic attitude

toward marriage is desirable for the perpetuation of the human race. In any event, sound information is in this book. It is reasonable to believe that, nature being what it is, the information will harm no one.

Medicolegal

Privileged Communications: Testimony of Physicians Unsuccessfully Attempting to Resuscitate Unconscious Patient.—Palmer went to his garage to work on his automobile. Three hours later he was found lying on the floor of the garage, unconscious, face downward, with bruises on his forehead and nose. Two windows of the garage were open, but the large doors were closed. When he was found, the motor of his automobile was running, and smoke and fumes pervaded the garage. Two physicians attempted to revive him but failed. Palmer was insured under an accident insurance policy which excluded from its coverage death from cerebral hemorrhage and from asphyxiation by carbon monoxide. Suit was brought to recover under the policy.

On behalf of the plaintiffs, two physicians testified that in their opinions, based on hypothetical questions, Palmer died, not from carbon monoxide poisoning, cerebral hemorrhage or any other condition not covered by the policy, but from concussion of the brain. The two physicians who, when Palmer was found unconscious, attempted to revive him, testified, over objection, to the presence in the body of the deceased of the cherry red color characteristic of carbon monoxide poisoning. The jury disagreed, but the court granted the defendant-insurer's motion for judgment in its favor notwithstanding the disagreement, and the plaintiffs appealed to the Supreme Court of Minnesota.

Whether the evidence of the plaintiff's two medical witnesses that the insured died of concussion of the brain withstood the test of cross-examination and was sufficient to make a case for the jury, said the Supreme Court, depended largely on whether or not the evidence established that the body of the insured presented the cherry red appearance characteristic of carbon monoxide poisoning. The coroner's testimony as to the color of the body and the blood was not conclusive, for it was not shown that he qualified as an expert with respect to such matters. The two physicians who tried to resuscitate Palmer testified, over objection, to the presence of the characteristic cherry red color, but whether their testimony was admissible depends on whether information obtained by them in the course of their professional relations to the deceased was or was not privileged. The Minnesota statute provides in part: "A licensed physician or surgeon shall not, without the consent of his patient, be allowed to disclose any information or any opinion based thereon which he acquired in attending the patient in a professional capacity and which was necessary to enable him to act in that capacity." Mason's Minn. St. 1927, section 9814, subd. 4. Most reported decisions hold that information obtained by a physician in performing an autopsy is admissible even under statutes that forbid the disclosure of communications between a physician and his patient. The present case, however, is wholly unlike one in which a physician performs an autopsy, because then the physician is present, not to treat or minister to the patient, but only to determine the cause of death. In this case, the insured was probably dead when the physicians began their treatment, but that is a matter of surmise only, deducible from the failure of treatment to resuscitate him, and in any event, the precise moment of death is not known.

If the patient had been resuscitated, anything that the physicians learned in treating him would have been privileged. If the patient was alive when they commenced treatment but died during treatment, all would agree, the Supreme Court thought, that the information obtained was privileged. How can it be different, then, said the court, in a case in which the attending physicians do not know whether the patient is or is not beyond hope of revival? To say that in such a case the admissibility of the evidence obtained by the physicians depends on the results of their treatment, rather than on the purpose of the physicians in administering treatment, would be absurd. Privilege, so far as it related to objective symptoms, the court thought,

would be largely nullified, if the physician was compelled to tell what he saw the moment after death.

In the opinion of the Supreme Court, the testimony of the physicians who attended the insured when he was found unconscious was privileged and should not have been admitted. In the absence of the evidence of those physicians, the opinions of the physicians who testified on behalf of the plaintiff, said the court, justified the theory that the insured died from concussion of the brain, and the presumption followed, in the absence of proof to the contrary, that the violence that caused the fatal concussion was the result of accidental means. The judgment of the trial court in favor of the defendant-insurer was therefore reversed.—*Palmer v. Order of United Commercial Travelers of America (Minn.)*, 245 N. W. 146.

Workmen's Compensation Acts: Death from Cerebrospinal Meningitis Compensable.—The *President Madison* arrived in Seattle, March 11, 1929, with several cases of cerebrospinal meningitis on board, which had developed in the steerage. On the same day, the deceased, a steamfitter, in the course of his employment, was on the deck of the ship, above the steerage passengers, who had been kept in their quarters. Later these passengers were removed, and the ship was fumigated, March 13. Between March 14 and 21, the deceased and others were engaged in making repairs to the ship, and on the last day he was at work in the steerage for about a quarter-hour. Between March 24 and 26, while on an automobile trip, he was tired and drowsy, and on the day after his arrival at his destination, March 27, he became ill. He died of cerebrospinal meningitis on the following day. Under the Longshoremen's and Harbor Workers' Compensation Act, an award was made in favor of his widow and minor child. From a judgment in the United States district court affirming that award, his employer, the Todd Dry Docks, Inc., appealed to the United States circuit court of appeals, ninth circuit.

The appellant did not seriously question the claimant's contention that the deceased contracted cerebrospinal meningitis on the ship and did not deny that cerebrospinal meningitis is a disease resulting from infection, within the meaning of the act, which provides:

The term "injury" means accidental injury or death arising out of and in the course of employment, and such occupational disease or infection as arises naturally out of such employment or as naturally or unavoidably results from such accidental injury, . . .

The only question to be decided, therefore, was whether the fatal cerebrospinal meningitis was the result of an injury within the meaning of the act.

The appellant admitted that the phrase "such . . . infection as arises naturally out of such employment" would include infectious diseases contracted in the course of employment, but contended that an infectious disease, to be compensable, must be based on an *occupational* infection; that is, that the phrase "such occupational disease or infection" should be construed to mean "such occupational disease or *occupational* infection." Impliedly, the appellant contended that the cerebrospinal meningeal infection in the present case was not an *occupational* infection and therefore was not compensable. The court, however, declined to accept the appellant's contention, except to the extent that the qualifying words of the statute, "infection as arises naturally out of such employment," implied an occupational relation. The court was satisfied that the death in this case resulted from an infection arising naturally out of his employment and affirmed the award in favor of the widow and minor child of the deceased.—*Todd Dry Docks, Inc., v. Marshall*, 61 Fed. (2d) 671.

Society Proceedings

COMING MEETINGS

American Association of Railway Surgeons, Chicago, August 10-12. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.
Montana, Medical Association of, Anaconda, July 12-13. Dr. E. G. Balsam, Box 88, Billings, Secretary.
Washington State Medical Association, Seattle, August 28-30. Dr. Curtis H. Thomson, 1305 Fourth Avenue, Seattle, Secretary.
Western Branch Society, American Urological Association, Vancouver, B. C., August 3-5. Dr. George W. Hartman, 999 Sutter Street, San Francisco, Secretary.

Current Medical Literature

AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk () are abstracted below.

American Journal of Diseases of Children, Chicago

45: 461-690 (March) 1933

- Congenital Syphilis. M. H. Roberts, Atlanta, Ga.—p. 461.
*Use of Placental Extract in Prevention and Modification of Measles. C. F. McKhann and F. T. Chu, Boston.—p. 475.
Effect of Milk and Modified Milk on Gastric Contractions. F. W. Schlutz and Dorothy Fetter, Chicago.—p. 480.
Determination of Iron Content of Blood in Children. I. P. Sobel and I. J. Dreker, New York.—p. 486.
Intestinal Infections in Infants and in Children—1930 and 1931 Series. Marion M. Johnston, A. Brown and Mildred J. Kaake, Toronto, Canada.—p. 498.
Etiology of Mongolism. R. L. Jenkins, Chicago.—p. 506.
*Elevations of Temperature in the Newly Born. L. R. DeBuys, New Orleans; H. L. Bacal, Montreal, Canada, and Amelie M. Stewart, New Orleans.—p. 520.
Motility in Young Infants: I. Relation to Body Temperature. O. C. Irwin, Iowa City.—p. 531.
Id.: II. Relation to Two Indexes of Nutritional Status. O. C. Irwin, Iowa City.—p. 534.
*Infant Nutrition: VII. Lactic Acid Milk; Has It Solved the Problems of Infant Nutrition? J. R. Gerstley, Chicago.—p. 538.
Renal Tuberculosis in Juveniles. M. F. Campbell, New York.—p. 555.

Placental Extract in Measles.—McKhann and Chu gave placental extracts, by intramuscular injection, as a prophylactic measure to forty-three children who had not experienced measles and who had come in contact with the disease. The extracts represented a concentrated preparation of the globulins of the fetal and maternal blood contained in the placenta together with some placental tissue protein. In no instance did the intramuscular administration of placental extract appear to be without effect in either prevention or modification of measles in nonimmune contacts, and in no instance was there a general or local reaction or evidence of local infection following the injection of placental extract. In these cases the effective dosage (from 4 to 10 cc., depending on the age of the patient and intensity of exposure) of the extract was slightly more than the usual dosage of convalescent serum.

Elevations of Temperature in the New-Born.—From a ten year study of the temperatures of new-born infants, DeBuys and his associates conclude that early rises of temperature are indicative of either trauma or inanition. If the peak of the temperature corresponds in time with the maximum loss of body weight, the fever is due to inanition; if there is no relation between the two except that the maximum loss of body weight follows the temperature curve, the cause is trauma. The duration of the elevated temperature in these two types of cases is from one to three days. The prolonged elevated temperatures of from three to nine days or more may be found in the diseases of the new-born and in some instances of trauma. Elevated temperatures retard the progress of the new-born, and the higher and the longer the elevated temperature, the greater its influence on retarding the progress of the infant, as shown by the excessive loss of body weight and the delayed return to the initial weight. When fever appears and there is a relation between elevated temperature and loss of body weight as well as prompt improvement following the administration of soluble carbohydrates and alkalis, the case is one of inanition. If there is no response to this treatment there must be some other influencing factor such as trauma. If there is fever without relation to loss of body weight and no response to the administration of soluble carbohydrates and alkalis, the cause is trauma, the degree of which will influence the course of the illness. It is possible that a combination of conditions may cause an elevated temperature. There seemed to be a relation between trauma and the hemorrhagic disease of the new-born in the authors' series, also between the toxemias of pregnancy and the hemorrhagic disease

of the new-born, and acute inanition has been found associated with each of the causes of elevated temperature.

Infant Nutrition.—Gerstley gave six babies feedings of breast milk, breast milk and 12 per cent lactose, whole cow's milk, whole cow's milk with 3 per cent and later 12 per cent lactose, lactic acid milk, lactic acid milk with 3 and 12 per cent lactose and 12 per cent of a maltose-dextrin preparation. The stools of infants fed lactic acid milk resembled those of infants fed whole cow's milk and not those of infants fed breast milk. It was necessary to add the same amount of lactose to whole lactic acid milk (12 per cent) as to whole cow's milk to overcome its alkalinizing effect on the stool. The addition of 12 per cent of a maltose-dextrin preparation to lactic acid milk gave no different results than when added to whole cow's milk. The urine of the babies fed whole cow's milk or whole lactic acid milk showed traces of albumin, casts and sugar more frequently than that of breast-fed infants, but these changes were transitory. In discussing the results from the point of view of the gastrointestinal tract, the analyses suggest that: 1. The digestion of whole lactic acid milk demands as much of the intestinal digestive juices as does whole cow's milk, or more. 2. The addition of lactic acid to whole cow's milk does not increase the amount of lactic acid in the intestine nearly as much as does the addition of lactose. 3. The question is reopened as to whether the benefit of the addition of acid may not be due to the lipase. The author concludes that whole lactic acid milk is as easy of gastric digestion as breast milk but that it does not alter the effects of a diet of whole cow's milk on the intestine and may not on the body; it usually leads to overfeeding, and it is a method of feeding that brings a direct challenge to the theories of metabolic injury so beneficial to the development of pediatrics during the last twenty years.

American Journal of Physical Therapy, Chicago

10: 1-36 (Feb.) 1933

- *Treatment of Women with Diathermy. W. S. Pugh, New York.—p. 5.
Painful Feet. W. Martin, Atlantic City, N. J.—p. 8.
The Almond in Nutrition. D. E. Lane.—p. 11.
Is Walking a Lost Art? N. D. Mattison, New York.—p. 17.

Treatment of Women with Diathermy.—Pugh states that diathermy is an ideal method for the treatment of gonorrheal infections of the urethral and cervical canals and their complications. All treatment must be conducted by a physician; it should never be entrusted to a so-called technician. Diathermy is painless, if the operator keeps within proper bounds, and the procedure is uncomplicated. The author's observations, coupled with those of others, show cure in at least 70 per cent of these cases. The basis for the application of diathermy in gonorrhea is the fact that the gonococcus is unfavorably influenced by fever. There are two forms of diathermy, the medical or sedative, with a maximum temperature of 50 C., and the surgical or destructive, used at a much higher temperature. The author uses the sedative form in the treatment of gonorrhea.

- Treatment of Bronchial Suppuration and Pulmonary Abscess by Bronchoscopic Drainage: Report of Cases. J. W. Miller, New York.—p. 390.

Complications of Otitis Media.—Love states that otitis media and mastoiditis with intact membrana tympani occur more frequently than is generally supposed. Infection may extend from the middle ear to the mastoid and intracranially without gross pathologic changes in the middle ear. *Streptococcus haemolyticus* is probably the most frequent and most dangerous bacterial agent in the most severe cases. Minute examination of the ear canal and drum is imperative, and any deviation from normal should be viewed with suspicion. It is important to exhaust every available diagnostic measure in order to come to an accurate conclusion. The condition is more common in children than in adults. The causes of failure in diagnosis are: (1) an insufficient history, (2) a failure to associate a distant manifestation with a possible otitis, (3) a lack of proper evaluation of minor anatomic changes in the external canal and the ear drum, and (4) an insufficient follow-up of potentially dangerous cases. Swimming is a frequent cause of this type of disease. The expression "sagging of the canal wall" should be deleted from otologic usage and the term "edema" substituted, which describes accurately its location and extent.

Surgery of the Nose and Sinuses.—From his experiments on fifteen dogs, Hilding draws the following conclusions, at least as far as the normal frontal sinus of the dog is concerned: 1. High ridges and diaphragms of scar tissue follow the removal of strips of mucous membrane on concave surfaces. 2. These ridges and diaphragms interfere with normal drainage and cause mucin to collect in pools if they are so placed that the mucin cannot readily slide around them. 3. When a complete ring of mucous membrane is removed from the inside of the sinus in any plane, dividing the remaining mucous membrane into halves, the circular scar that forms in healing may become a complete diaphragm of connective tissue, dividing the sinus into two cavities. In that case, one of the cavities subsequently becomes filled with mucin. 4. Partitions, or septums, between sinuses can be removed, and the resulting opening can be caused to remain patent, as made, if the edges of the mucous membrane on both sides of the partition are made to meet, and no strip of bone is left bare. 5. On the other hand, if at the end of the operation a bare strip of bone encircles the opening, a diaphragm forms in healing that usually closes the operative opening and makes the partition or septum intact once more. 6. The ostium

can be closed by removing a circular strip of mucous membrane from around it.

Solitary Neurofibroma of Pharynx.—Figi reports the case of a woman, aged 61, who presented herself at the author's clinic because of frequent sore throat and persistent irritation in the throat, together with partial obstruction of the left nostril. Examination disclosed extreme prominence of the left tonsil. Tonsillectomy was advised. At operation the tonsils were found to be uniform in size, the bulging on the left being due to a large, firm, somewhat irregular mass situated external to the aponeurosis. The tumor was not incised when the tonsil was removed. The growth was thought to be a carcinoma of the mixed tumor type, and removal following preliminary ligation of the external carotid artery was carried out four weeks later, with the patient under intratracheal anesthesia. Grossly, the tissue was of moderately firm consistency and yellowish. It appeared to be fibro-elastic tissue undergoing degeneration. Microscopically, the tumor was reported to be a degenerating neurofibroma. The author concludes that such tumors arise from the sheaths of nerves or from nerve roots. They are more commonly situated centrally, that is, on nerve roots, in contradistinction to the tumors of neurofibromatosis, which are, as a rule, found peripherally. Occurring within the cranial cavity or the spinal canal, they arise most commonly from the root of the eighth cranial nerve or from the roots of the spinal nerves, more commonly the posterior roots. They occur rarely on other cranial nerves, especially the optic and trigeminal.

Treatment of Cancer by Radiotherapy.—Richards points out that, apart from the urgent importance of early diagnosis, there are few things of greater moment to the victim of malignant disease than is the first line of treatment adopted in dealing with his disease. A condition that materially complicates the treatment of epitheliomas is previous unsuccessful treatment. Frequently these lesions have been repeatedly cauterized by chemical, thermal or electrical methods, or they have been unsuccessfully treated by roentgen rays or radium. In any such case the possibility of completely and permanently healing the lesion is definitely diminished and may be completely lost. The question of excision constantly comes up for consideration in connection with any or all of the lesions of external cancer and there are some surgeons who still practice excision and then refer the patient for postoperative irradiation of some sort. The radiologist feels that in the majority of cases the excision is unnecessary and in a considerable number will result in more scarring than would have otherwise been the case. This is especially true about the face, in which it may be difficult or impossible to perform an excision sufficiently wide to be certain of curing the disease without extensive scarring. If under these circumstances an excision is practiced, it is usually too restricted and dependence must necessarily be placed on irradiation to prevent recurrence. In such a case the responsibility for preventing the recurrence is placed entirely on the radiologist, who could, by the same procedure by which he undertakes to prevent the recurrence, have cured the lesion in the first instance.

Tumors of Extrahepatic Bile Ducts.—According to McLaughlin, benign tumors of the extrahepatic bile ducts are uncommon, while malignant tumors occur in a ratio of approxi-

mately 1:4 to gallbladder carcinoma. Gallstones are present in one third of the cases and are probably an important etiologic factor. Men are more frequently affected than women; the ratio is 3:2. The illness usually begins during the fifth or sixth decade with painless progressive jaundice. Early surgical intervention offers the only hope of relief. The surgical treatment of cholelithiasis, with or without symptoms, would seem indicated if the mortality from bile duct and gallbladder carcinoma is to be reduced.

Pseudomyxoma Peritonei of Appendix.—Pitts and Gee report the case of a man, aged approximately 50, in whom a diagnosis was made of colloid carcinoma of the stomach, with extensive metastases, rendering operation inadvisable. The patient was given symptomatic treatment, chiefly for frequent vomiting and gnawing abdominal pain. Enemas occasionally gave some relief. Considerable morphine was finally required. Bronchopneumonia developed and he died two months later. The diagnosis at necropsy was extensive pseudomyxoma peritonei, originating from a mucocoele of the appendix; calculous pyonephrosis (left); bronchopneumonia (right). On microscopic examination of many of the sections, small islands of tall, columnar, mucus-producing epithelium could be found in locations quite remote from the appendix, and this fact would suggest that they are implants of appendiceal mucosa that have retained their secretory function in their new environment. While this process is not histologically malignant, it is certainly so in its manifestations. There appear to be no criteria by which a preoperative diagnosis may be made, and even at laparotomy a diffuse colloid carcinoma of gastric or colonic origin cannot be excluded without a thorough exploration of these sites. When the condition is so advanced, the prognosis would seem to be absolutely unfavorable.

Administration of Iron.—Lucas and Henderson prepared a fairly stable syrup of ferrous chloride in their laboratory and it was administered orally to patients with anemia by Farquharson. The amount given was approximately $1\frac{1}{2}$ grains (0.1 Gm.) daily. The clinical results obtained by Farquharson in a limited number of cases seem to justify the claims made by other investigators. The authors' formula for the syrup is 1.13 Gm. of reduced iron, 20 cc. of dilute hydrochloric acid and enough syrup to make 120 cc. The dosage is 3.5 cc. of the syrup three times daily after meals. The syrup will keep for about a month under ordinary conditions, if protected from direct sunlight. It may become a very pale yellow, but only a trace of ferric iron is present. Each drachm dose contains approximately one-half grain (0.03 Gm.) of iron in the form of ferrous chloride.

Thomas Sydenham as Epidemiologist. A. Somerville, Toronto.—p. 79.

Sterilization of Eating Utensils. R. St. J. MacDonald and Grace M. Freeborn, Montreal.—p. 83.

Acute Intestinal Intoxication.—Brown states that intestinal intoxication, a disease of the autumn months, is characterized by diarrhea, vomiting and drowsiness. The blood serum in acute intestinal intoxication shows a decrease in bicarbonate, that is, an acidosis. This is due to loss of base through diarrhea and vomiting, and a piling up of acids through failure of excretion. Loss of chlorides through vomiting, and a reduced amount of serum through loss of water, modify the acid base concentration. The routine treatment of acute intestinal intoxication, as carried out in the author's hospital, consists of the direct transfusion of 15 cc. of whole blood per pound of body weight; the parenteral administration of 10 cc. of fluids per pound of body weight, one fourth of the amount being administered in the form of physiologic solution of sodium chloride, and three fourths as a 5 per cent dextrose solution, and sodium citrate, orange juice and dextrose solution, or a 15 per cent dextrose solution by mouth until the toxicity has disappeared, when the solution can be replaced by diluted evaporated milk or protein milk formulas.

Lipids of Blood Plasma in Epilepsy.—McQuarrie and his associates determined the lecithin, cholesterol and total fatty acid of the blood plasma in a group of 100 epileptic and 32 non-epileptic children under essentially the same conditions. No significant difference was found in the range of values for cholesterol or in its variability in the two groups. The mean value for lecithin was found to be significantly lower and that for total fatty acid significantly higher in the epileptic patients than in the nonepileptic control subjects. Both the phospholipid and the total fatty acid values showed significantly greater variability in the epileptic than in the nonepileptic children.

Sedimentation Rate of Red Blood Cells in Arthritis.

—In order to determine the value of the sedimentation rate of the red blood corpuscles in the differential diagnosis and prognosis of arthritis, Oppel and his associates studied this reaction in 107 patients with various forms of arthritis. During the same period, 103 patients with miscellaneous diseases were studied as a control group. There were great variations in the various forms of arthritis. The most rapid rates were seen in acute rheumatic fever, rheumatoid and gonococcal arthritis and the febrile diseases. Patients with rheumatoid arthritis showed a more rapid sedimentation rate than the group with degenerative arthritis, but there was no striking difference between the two groups. Of the patients with other forms of arthritis, those with rheumatic fever showed the most rapid rates, but it was impossible to differentiate the cases of rheumatic fever with arthritis from other cases of acute arthritis from an examination of the sedimentation rate. The reason for the great variation in the same disease is probably the changing state of the patient and the stage of the disease when the examination is made. The authors observed that, as patients with acute rheumatic fever improve, the sedimentation rate decreases. This was true also in some cases of rheumatoid arthritis. In the case of rheumatoid arthritis there were variations in the rate in the same patient

but they were less striking, and there was a greater tendency for the rate to remain elevated for longer periods. This is to be expected, as the disease is chronic. In some patients, increases in the rate were observed without any noticeable increase in the severity of the arthritis, and, in other patients, clinical improvement was not followed by a decrease in the sedimentation rate even over a period of several months. The test is of value in following the course of some diseases, such as acute rheumatic fever and rheumatoid (atrophic) arthritis.

Anemia of Infancy.—Strauss made examinations of the blood, within forty-eight hours after birth, of fifteen infants whose mothers exhibited less than 45 per cent hemoglobin at the time of delivery and of twelve infants whose mothers presented more than 70 per cent hemoglobin. The average hemoglobin of the first group of mothers was 36 per cent and of the second group 76 per cent. The anemia of the first group was of the hypochromic type. The author observed that infants born to women suffering from hypochromic anemia exhibit a normal picture at birth but develop moderate to severe degrees of anemia during the first year of life. This form of anemia may be prevented by administering iron to the mothers during pregnancy or may be corrected by administering iron to the anemic infants. It is believed that this form of anemia is due to deficient storage of iron by the fetus dependent on a deficient supply of this element in the mother.

Bacteriologic and Serologic Study of Dysentery.—Soule and Heyman report a study of eighty-nine cases of an acute epidemic of diarrheal disease. Eighty-four of the patients were under 8 years of age and sixty-four of this group were less than 2 years old. Organisms belonging to the dysentery group were isolated from sixty of these infections. The authors present a detailed study of the morphologic, cultural, fermentative and serologic reactions of the various strains isolated. The cultures on the basis of these reactions are classified into three groups. Type I appears to be identical in its fermentative and serologic reactions with *Bacillus dysenteriae* Flexner. This type was found most frequently during the epidemic, occurring in twenty-six cases, eight of which terminated fatally. Type II corresponds, colony formation excepted, to *B. metadysenteriae* Castellani and is identical with *B. dysenteriae* Sonne. Members of this group were isolated from seventeen cases in which the clinical manifestations were severe but, in contrast to infections with the Flexner type, were not fatal. Type III, based on fermentation reactions, is closely related to *B. morganii*. However, from the observation that this type was present in four of the fatal infections in which the Flexner organism was the causative agent, it is considered that type III is a variant of type I. Considerable experience on the part of the authors with the mucoid variants of the members of the colon-typhoid-dysentery groups of organisms lends further support to this view. The data indicate that there were two definite serologic groups, *B. dysenteriae* Flexner and *B. dysenteriae* Sonne, among the three types isolated and that they were the causative agents of the present epidemic of infantile dysentery. On the basis of priority, the authors suggest that the name *B. dysenteriae*

Castellani-Sonne be given to the members of the type III dysentery organism of Thijotta.

Checking Solutions of Procaine Hydrochloride.—In view of the not infrequent occurrence of cocaine and procaine poisoning from the use of solutions of higher concentrations than intended; Co-Tui and Benaglia present a simple test, which consists in taking 2 cc. of the reagent, adding 5 drops of the indicator, shaking, then adding 1 cc. of the anesthetic solution to be checked, and shaking again. The resulting color change is compared with the standard chart. The average time for performing this test is thirty-five seconds. The color developed in the tube by the addition of 5 drops of the indicator is deep blue. Comparison should be made in reflected artificial light. Any concentration higher than 2 per cent renders the resulting mixture colorless. Intermediate strengths cause the development of intermediate shades. A definite color is produced with 1 drop of the mixed indicator, but because of the fact that the color developed in transmitted light is different from that in reflected light, 5 drops of the indicator are used to intensify the color to such an extent that light transmission through the solution is largely eliminated. The formula for the reagent is 5.3 Gm. of anhydrous sodium carbonate and 1,000 cc. of distilled water. The formula for the indicator consists of 1 Gm. of thymophthalein, 0.05 Gm. of phenolphthalein and enough 70 per cent alcohol to make 100 cc. The color chart can be made by any local artist from the changes observed by making a series of 2.5, 2, 1 and 0.5 per cent concentrations of procaine hydrochloride.

Hypoplasia of Aorta.—Ikeda presents four cases of hypoplasia of the aorta terminating in death. In each instance, necropsy disclosed a cardiac hypertrophy with relative dilatation, without any other demonstrable lesions except a small aorta. In none of the four cases were congenital anomalies involving the genital apparatus, heart or any other visceral organs found. The author reviews the literature and formulates diagnostic criteria from several of the authors. Hypoplastic aortas that cause no cardiac symptoms have been encountered from time to time, only to be overlooked or disregarded by the examiner. No plausible explanation has been advanced for the evident

dilemma that, whereas a group of persons showing a hypoplastic aorta manifest definite cardiac symptoms or die of sudden heart failure, many others evidently show no signs of cardiac involvement. The author concludes that in the light of our present knowledge it would seem reasonable to state that there is a sufficient basis for assuming, until otherwise proved, that hypoplasia of the aorta may be a major factor in the causation of cardiac hypertrophy and subsequent sudden failure and death in young, robust persons who show no other demonstrable lesions at necropsy.

Pulmonary Tuberculosis.—Padgett states that the beneficial effects of surgical compression of pulmonary tissue is largely explained on the basis of the physiologic effects of rest and collapse of cavitation. There is some difference of opinion as to the efficiency of hemidiaphragmatic paralysis. The evidence, however, indicates that as an independent procedure phrenicectomy is of value in basal tuberculosis, especially in unilateral tuberculosis of the productive type, and that symptomatic relief may follow in certain selected cases with distressing symptoms caused by the pull of adhesions on vital structures and also in certain cases with hemoptysis. Phrenicectomy is often of value as an accessory procedure to incomplete pneumothorax, when basal or lateral adhesions are preventing collapse, and after a pneumothorax, before the lung is allowed to reexpand, or to prolong the refill interval after pneumothorax. Most observers agree that the operation is indicated preliminary to thoracoplasty. Phrenicectomy in properly selected cases of unilateral tuberculosis of the productive type may benefit as high as 50 per cent, and the operation should fulfil the expectations of the surgeon in about 75 per cent of the times when it is used as an accessory operation. In general, in an otherwise hopeless group of patients, the operation of paravertebral thoracoplasty is of great value in three groups of cases: (1) in pulmonary tuberculosis of the predominantly fibroid type, usually with but also without cavitation, and with the active lesion limited to one lung; (2) following unsatisfactory pneumothorax when an adherent upper lobe prevents apical compression or when a band of adhesions prevents collapse of some essential area, and (3) after a tuberculous empyema of one variety or another has developed which resists conservative treatment (aspiration). The expectation after extrapleural thoracoplasty for pulmonary tuberculosis, provided a proper selection of patients is made, is that about one tenth fail to recover from the operation; about one half become clinically free from symptoms and are restored to work; another third improve, and the remainder die from the progress of the disease.

Chronic Arthritis of Knee.—Kauffmann points out that the treatment of arthritis of the knee is no different from that of arthritis of any other joint. The salicylates are the most important drugs used. Because of the small amount that can be administered by mouth or intravenously, he uses neither of these two methods: he prefers giving the drug by rectum. The advantage is that mammoth doses can be taken without gastric upset. On the first day he gives from 100 to 150 grains (6.5 to 9.7 Gm.) in 4 ounces (120 cc.) of water by rectal drip, followed by an enema during the morning and evening. On the second day he gives two doses of from 150 to 200 grains (9.7 to 13 Gm.). On the following days he gives from 200 to 250 grains (13 to 16.2 Gm.) twice daily in 6 ounces (180 cc.) of water. The amount of the drug will depend on the condition of the patient. This form of treatment is especially useful in acute rheumatic fever and when the pain is severe. At the Mayo Clinic the

rectal method is used, the salicylates being injected in a paste. The most important form of hydrotherapy in arthritis of the knee is the contrast baths, for which a pan of hot water and one of ice water and two bath towels constitute the apparatus needed. The hot towel is wrapped around the painful joint for one minute, and then the ice towel is applied for the same length of time. This is continued for twenty minutes and is done twice daily. Two types of vaccines are used in the treatment of arthritis, the specific and the nonspecific. The use of the former presupposes a correct bacteriologic diagnosis. This consists of taking cultures of material from a supposed focus in the patient's whole blood under the supposition that only the pathogenic bacteria will grow, there being enough resistance in the blood to inhibit the growth of the saprophytic organisms. The most successful form of nonspecific vaccine is the typhoid, and the triple typhoid vaccine is most commonly employed. The initial dose is 25,000,000 intravenously. In patients aged more than 50 it is best to begin with the smaller doses, ten or fifteen million. The second injection is twice the size of the first, and to each following one is added the amount of the original dose. One must naturally be guided by the severity of the reaction. The treatments are given twice weekly for six treatments. If there is no rise in temperature following the fourth injection, it is useless to continue. If improvement has been noted at the end of the series, it is best to wait several weeks and start a new series, this time beginning with the amount that will cause a mild reaction. Because of the reactions that follow, these patients should be kept in bed or, better, in the hospital.

Bismuth Arsphenamine Sulphonate in Treatment of Syphilis.—Beckman states that bismuth arsphenamine sulphonate is slower than the older drugs in causing the disappearance of spirochetes from primary lesions and also in bringing about the healing of both primary and secondary lesions. It is, however, apparently effective in "curing" seronegative primary syphilis and compares favorably with the older drugs in reducing seropositive primary cases to negative. Bismuth arsphenamine sulphonate has not definitely established itself as equal to the older drugs in preventing relapse in seropositive primary and secondary cases. The healing of the lesions of tertiary syphilis is accomplished more slowly by bismuth arsphenamine sulphonate than by the older drugs, but it provides a good means of testing the arsenic sensitiveness of patients who have had much previous treatment. The efficacy of the drug in reversing the blood Wassermann reaction in chronic syphilis is not yet definitely determined, but it has undoubtedly an excellent tonic effect in these cases. The pain in tabes dorsalis, and particularly the headache in acute meningeal syphilis, is often considerably relieved by the drug. Cases of congenital syphilis with active lesions respond more slowly to bismuth arsphenamine sulphonate than to the older drugs, which is also true of cases of interstitial keratitis. The ultimate effects, however, and also the serum reversal effect, are satisfactory. Local reactions of pain and stiffness follow about 2 per cent of the early injections during a course of treatment. Bismuth arsphenamine sulphonate has apparently a lower systemic toxicity than arsphenamine, perhaps even than neoarsphenamine,

and has been on the whole satisfactorily substituted for the older drugs in cases of arsphenamine sensitiveness. However, it is capable of causing grave injury to the hematopoietic system, and it is also probable that it cannot be safely substituted for the older arsphenamines in instances in which their use has given rise to an exfoliative dermatitis. The incidence of exfoliative dermatitis primarily caused by bismuth arsphenamine sulphionate is low.

Subarachnoid Anesthesia and Procaine Hydrochloride.

—According to the experiments of Co-Tui on dogs, respiratory stoppage due to paralysis of the respiratory center occurs when procaine hydrochloride is introduced into the subarachnoid space in sufficient dosage. This dosage is not a fixed one but varies with different body states. Some narcotics and disease conditions make the center more sensitive to the paralyzing effect of procaine. The statement often made that spinal anesthesia is perfectly safe in bad risks is not confirmed by the author's experimental work. When complete paralysis of both the respiratory and the vasomotor centers occurs, artificial respiration and the intravenous injection of ephedrine are effective as measures of resuscitation. Hospitals in which spinal anesthesia is employed must be prepared to counteract paralysis of the medullary centers; that is, an artificial respiration equipment and measures for sustaining blood pressure must be at hand.

Resuscitation.—Flagg points out that the only method of resuscitation offering hope of recovery, in the case of extreme asphyxia, absent respiration, absent reflexes, complete relaxation and failing circulation, is intratracheal insufflation of oxygen-carbon dioxide, under pressure, because this technic alone fulfils the three urgent and essential requirements for asphyxial relief. Anoxemia is overcome by the highly concentrated oxygen thrown directly into the absorbing area, the respiratory center is stimulated by the specific action of carbon dioxide, and the Herring-Breuer reflex is directly stimulated through the physical distention of the chest by the insufflated gas. In the case of the new-born, an additional vital benefit is conferred by the relief of antenatal atelectasis.

Sickness and Accident Insurance Problem: Suggested by California State Medical Society. M. P. Dorman, Seattle.—p. 116.

Postoperative Massive Collapse of the Lung.—The Faulkners point out that massive collapse of the lung is caused by the presence of excess intrabronchial secretion and exudate. In general surgical conditions this secretion is aspirated during and following the operation, whereas in patients with previous pulmonary disease the pus is present within the tracheobronchial tree before any type of surgery is instituted. Aspirated material may cause bronchial obstruction and atelectasis by acting mechanically as a foreign body or by setting up an infection of the bronchial mucous membrane so that the resultant edema shuts off the air flow. The movement of this secretion within the lung, with changes in the posture of the patient, has been designated as "internal drainage" and accounts for the site of the atelectasis and the migrations, recurrences and response to

treatment. Postoperative massive collapse of the lung may be prevented by adopting measures to lessen the chances of aspiration, plugging of bronchi, obstruction of the air flow and the spread of infection within the lung. To obviate the onset of atelectasis, patients with pulmonary abscesses, bronchiectasis and pulmonary tuberculosis should have bronchoscopy before and after operation, to remove the excess secretion and exudate and to prevent spilling within the tracheobronchial tree. The posture during and following operation should be such as to accomplish the same end. In general surgery the Trendelenburg, head down, position is recommended; atropine is administered preoperatively to lessen the amount of secretion; oral and nasopharyngeal secretions are removed by suction; and the toilet of the mouth is such that the undesirable effect of aspiration will be lessened decidedly. Treatment is based on the removal of collected intratracheal or intrabronchial secretion. This is facilitated by the administration of saturated solution of potassium iodide, and, when the patient cannot expectorate the material by cough and postural exercises, the bronchoscope is to be used.

Pruritus Ani.—Tashian states that, in pruritus ani, at the stage of chronic dermatitis he has been able to mobilize histiocytes and effect a cure, provided the causative factors have been taken care of. Three solutions are effective stimuli in calling forth these defense cells in great numbers. They are sterile broth solution, hemoglobin, and triply distilled water. Whether the chronic productive obstinate dermatitis is due to bacteria or their toxins, to chemical or osmotic changes, or to lowered resistance, "nutrient broth" seems to be the most innocuous and effective mode of treatment. It attracts the histiocytes in the greatest numbers compared to other solutions (nutrient broth: 3 Gm. of meat extract, 10 Gm. of peptone, and 8 Gm. of sodium chloride adjusted to pH 7.2). The pruritic area should be cleansed with ether and alcohol and painted with iodine. The solution is injected with a hypodermic syringe having a fine needle, 1½ inches long, from the periphery toward the orifice of the anus, fanwise, dividing the circle into six quadrants, and 5 cc. of the solution being injected at each site. This is followed with subcutaneous injections of 1 cc. each, centrifugally all round the anal orifice, about 1 inch distant from the center, until all the wrinkles are smoothed out. This should be repeated every three days for four consecutive treatments. Then, after a lapse of two weeks, the same course of treatments should be repeated.

Penetrating Wounds of Thorax.—Bigger states that penetrating wounds of the thorax are necessarily serious because of the important structures which are apt to be injured. A large percentage of patients with such wounds will recover if treated conservatively, but some will require operation, that is, those with wounds of the heart and great vessels, wounds of the vessels of the chest wall, sucking wounds, and those with

valvular pneumothorax. Any patient who has sustained a penetrating wound in the cardiac area with evidence of beginning circulatory failure should be studied carefully and, if the symptoms and signs of cardiac injury are present, should be operated on immediately. Injury to the vessels of the chest wall is difficult to diagnose, but if there is evidence of continued intrapleural hemorrhage, thoracotomy should be done and the hemorrhage controlled. Sucking wounds should be closed as soon as possible. If there is a closed pneumothorax with marked mediastinal displacement and respiratory embarrassment, aspiration of air should be done; and if this reaccumulates rapidly, continuous decompression by an intercostal tube is indicated. Patients with blood in the pleural cavity should be treated conservatively in the early stages, unless the hemorrhage is so massive as to cause respiratory embarrassment, in which event the blood should be aspirated and partially replaced by air. In the author's series of forty-nine cases of penetrating wounds of the thorax, eight were wounds of the pericardium and intrapericardial structures. Six of the patients were operated on and four of the six recovered. Two were treated conservatively, with one recovery and one death. Thirty-four patients had intrapleural hemorrhage but only ten of these required aspiration. Three patients with large sucking wounds of the chest wall were operated on and all recovered. Of six patients with injuries to the larger vessels of the chest wall, five were operated on and the vessels ligated, and all recovered. In one patient with an injury to a posterior intercostal artery, ligation was not done and death resulted. Of five patients with wounds of the diaphragm, only one required suture. There were three infections of the chest wall; empyema developed in two of these and a lung abscess in one, as a result of the retention of an organic foreign body in the lung.

Prostatectomy and Transurethral Resection of Prostate.—Dodson presents a report based on the treatment of thirty-five patients, fourteen of whom were treated by open prostatectomy. One died in preparation for operation. Twenty were treated by transurethral resection. There were no deaths in the patients operated on by prostatectomy and the final results were satisfactory. There were two deaths in the group treated by transurethral resection. One of these, a patient with advanced carcinoma, died apparently from an unrelated cause. The other, a poor risk, died about a month after transurethral resection from cardiac failure. The average hospitalization for patients treated by open prostatectomy was fifty-four days, while the average hospitalization for patients treated by transurethral resection was thirty-five days, the majority of this saving of hospital days being due to the shortened postoperative period. Patients submitted to transurethral resection were in a better condition when discharged from the hospital than those treated by open prostatectomy. They were more robust and, as a rule, had better bladder function. The author believes that if routine open prostatectomy had been done on all these patients a higher mortality would have resulted.

Insulin Neuritis.—By "insulin neuritis," Caravati refers to subjective symptoms usually in the lower extremities, such as pains, numbness, tingling and thermal changes, which the patient complains of at a rather short interval after the beginning of daily injections of insulin. At times, though rarely, these discomforts are marked and continue as long as insulin is administered. When insulin is discontinued, the paresthesias usually disappear in three or four days, only to be manifest again after the resumption of insulin therapy. The author reports a case of insulin neuritis that was relieved by a change of the brand of the product. The author feels justified in concluding that idiosyncrasy to certain forms of insulin is responsible for the symptoms.

Perurethral Operations on Prostate.—According to Walker, perurethral methods of operation are of three kinds: electrocoagulation alone, electrocoagulation followed by a punch operation, and the removal of tissue by means of the McCarthy electrotome. The chief danger attendant on perurethral resection being sepsis, and sepsis being encouraged by remaining necrotic tissues, the McCarthy electrotome operation is the best. Perurethral resection necessitates the same attention to renal function and the same preliminary treatment as is required for the open operation. The key to success in perurethral surgery is the proper selection of cases. The most suitable for this method of treatment are cases of obstruction in which there is little total increase in the size of the prostate, cases in which for some reason or another enucleation is contraindicated, and some malignant cases of the scirrhous type.

Dextrose-Insulin Administration in Prolonged Narcosis.—Quastel and Ström-Olsen point out that the development of narcotic treatment in certain types of mental disease has been greatly retarded by the knowledge that prolonged narcosis for therapeutic purposes is often accompanied by toxic symptoms. They treated about fifty such cases with an alcohol-glycerin-aqueous solution of a mixture of diethylamine salts, 10 per cent barbitol and 10 per cent allylisopropylbarbituric acid, during the past two years. The results were encouraging except that toxic symptoms, including the production of ketosis, were demonstrated in a large proportion of the cases. The toxic by-effects were often so alarming that it became necessary to discontinue the treatment. The authors observed, from preliminary experiments, that the simultaneous administration of dextrose and insulin to narcotized animals brought about a decrease in toxicity of the narcotic, and this work led them to consider the possibility of the administration of dextrose and insulin to patients undergoing narcotic treatment. They have administered dextrose and insulin to twenty patients. The usual procedure has been to administer 2 cc. of a barbituric acid preparation intramuscularly from two to four times in twenty-four hours, most patients receiving three doses a day. The urine was collected in the morning and afternoon, and the morning specimen was always examined for acetone bodies. The Rothera nitroprusside test was used for the colorimetric demonstration of acetone, and in many cases acetone was estimated quantitatively. As soon as definite ketonuria appeared, the following modified procedure was adopted: Simultaneously with the next intramuscular injection

tion of a barbituric acid preparation, from 5 to 15 units of insulin was given hypodermically, and from then on this dose of insulin was administered two or three times daily (with each subsequent dose of the narcotic). With each insulin injection the patient received by mouth 50 Gm. of dextrose in water or milk. Blood sugar estimations were frequently made as a precautionary measure. The doses of dextrose and insulin cited have been, in the authors' experience, sufficient to avoid hypoglycemia. The immediate result of the insulin-dextrose modification of the narcotic treatment was the entire disappearance of ketonuria within forty-eight hours. The patients showed no ketonuria during the remainder of the course of the narcotic treatment, which lasted from fourteen to sixteen days. Toxic symptoms such as cyanosis, alarming drowsiness and vomiting disappeared partially or completely under the modified treatment.

Convulsions.—Newman believes that convulsions in children are due to congenital syphilis, pyrexia, rickets, meningitis, teething, phimosis, worms, and sometimes tetany. When the child is seen in a fit, three things must be done: The convulsions should be checked if possible; the fit should be prevented from recurring by giving from 5 to 10 grains (0.32 to 0.65 Gm.) of potassium bromide, in plenty of water as soon as the child can swallow, and the cause of the convulsion should be investigated, if it is not already obvious. Convulsions in adults are much more serious than in children and may be divided into two groups: those in which the patient is unconscious and those in which consciousness is retained. Consciousness is retained only in poisoning by strychnine and its allied preparations, in jacksonian epilepsy, in tetanus and in tetany. In strychnine poisoning, treatment consists in stopping the fits by chloroform anesthesia, washing out the stomach with a 1:1,000 solution of potassium permanganate, and leaving 20 grains (1.3 Gm.) of chloral hydrate in the stomach. Jacksonian epilepsy is not an emergency, but attention should be directed to the diagnosis and treatment of an organic lesion in or near the motor cortex. In tetanus the proper treatment is to stop the convulsions by chloroform anesthesia, under which the patient is put to bed and given 20 grains (1.3 Gm.) of chloral hydrate and 40 grains (2.6 Gm.) of potassium bromide by stomach tube (or double doses by rectum). The advantage of the tube is that half a pint of milk, two eggs and one-half ounce of dextrose can be left in the stomach at the same time. Thereafter the fits should be controlled by chloral, using chloroform if necessary, but the risk of toxic jaundice from repeated administration should be remembered. In treating a fit accompanied by coma, as soon as the convulsion ceases and the patient can swallow, a large dose of potassium bromide (one-half drachm [2 Gm.] in half a pint of water) should be given to prevent recurrence. If the fit continues, the patient should be anesthetized with chloroform and given a double dose of bromide by rectum. The emergency is dealt with and further treatment can be applied as indicated by the cause.

Acute Vomiting and Diarrhea in Children.—Moncrieff points out that all instances of acute onset of vomiting and diarrhea in children are cases of acute gastro-enteritis due to

bacterial infection; cases in which the cause is essentially irritation by food; cases of alimentary tract disturbance, in which a prolonged dietetic error is followed by the acute onset of vomiting and diarrhea, and cases of symptomatic diarrhea and vomiting. The basic principles of treatment are founded on the knowledge of the exact etiology of the symptoms in the individual case. The child must be treated as a whole. Too much attention to the character of the stools leads nowhere, and a fatal termination may ensue while the excreta are being subjected to detailed inspection. Skilled nursing is essential. A short period (from twelve to twenty-four hours) of starvation is necessary in every case, however mild, and even if the child is breast fed. Infectious precautions (as in typhoid) should be observed in all doubtful cases, and especially when blood and mucus are present in the stools. In infants, with a profound disturbance of water retention, the preliminary starvation period of from twelve to twenty-four hours must be occupied by the administration of copious quantities of fluid. If vomiting is a marked feature, the fluid should be given cold. The elimination of toxic substances in the intestine should be the next step. The author recommends a dose of castor oil (1 drachm [4 cc.] as a minimum). The lower intestine and stomach should be gently washed out with a weak solution of sodium bicarbonate or with physiologic solution of sodium chloride. Stimulants, such as camphor or epinephrine, are of value in collapse. At the end of the period of starvation, the ideal diet is the use of diluted human milk. When this is not available, a skimmed dried milk with the addition of a preparation of maltose and dextrin is indicated. A half cream dried milk diet forms a useful stepping stone between the skimmed milk regimen and the return to a full cream milk. Ordinary cow's milk is best avoided for some time, and all additions of fat to the diet, such as cream or cod liver oil, must be prohibited. In older children treatment is much simpler, as there is rarely the same gross disturbance of the water metabolism. The starvation period must be similarly observed and the return to food made gradually in the form of dilute milk and arrowroot, or one of the malted foods. Castor oil is useful, especially in the presence of abdominal distention, but its administration should not be permitted unless a diagnosis has been made for certain, and conditions such as appendicitis are excluded. In the dysenteric type, bismuth and opium should be used early to produce constipation.

Cutaneous Reactions in Acute Rheumatism.—Collis and his associates investigated the reactions of rheumatic and non-rheumatic children to the soluble extract of the ground-up bodies of hemolytic streptococci. The results indicate that: 1. Rheumatic children are more sensitive to this extract than are the nonrheumatic. 2. Of the rheumatic children, those with chorea are the most sensitive. 3. Children with active acute rheumatism, and for a period of six months after the acute attack after which their reactivity diminishes, show a high proportion of strongly positive reactions (80 per cent). 4. Children with fulminating carditis lose their skin reactivity during the severe phase of their illness, though they tend to regain it later. Patients with chronic cardiac failure also tend to give much reduced reactions. 5. Age (to that of puberty) is an important factor in determining the probability of positive reactions. 6. Skin reactions to hemolytic streptococcus extract appear to bear no relation to skin reactions with hemolytic streptococcus exotoxin (Dick toxin). The authors' comparative study of the skin reactions of extracts of hemolytic, green and non-methemoglobin forming streptococci indicates that these extracts do not contain a common active principle but that each extract

gives a specific skin reaction. Rheumatic children, when tested with extracts of two viridans streptococci and one gamma streptococcus, showed a higher percentage of strongly positive reactions to one of the viridans extracts than did the controls. Skin reactions of rheumatic children to tuberculin, Schick toxin and extracts from pneumococci, staphylococci, diphtheroid bacilli and Pfeiffer's bacillus do not show a higher sensitivity than do nonrheumatic children and thereby differ from the skin reactions produced by hemolytic streptococcus extract.

Idiopathic Steatorrhea.—Bennett and his associates observed fifteen adult patients suffering from celiac disease or idiopathic steatorrhea. They presented the following features: fatty stools, dilatation of the colon, tetany, osteomalacia, anemia, skin lesions and infantilism. Steatorrhea and disturbances of calcium metabolism were alone common to the whole group. Changes in the skeleton were found in all cases investigated. Roentgenograms showed osteoporosis and often florid rickets. In three cases, histologic examination of portions of bone showed osteoporosis and osteomalacia. Glossitis occurred in five cases, and achlorhydria in two of the twelve examined. Six of eight patients showed dilatation of the colon, and in two this assumed the proportions of megacolon. Diarrhea was present in five cases and had occurred in the past in twelve. Tetany was present in fourteen cases, skin lesions in seven, and clubbing of the fingers in nine. Slit lamp examination of the lens of thirteen patients revealed opacities in six: in no instance did the opacity interfere with vision. The blood picture was normal or showed hypochromic anemia, hyperchromic megalocytic anemia, or erythroblastic anemia. No relation between the type and severity of the anemia and other symptoms was established. The hyperchromic megalocytic anemia responded to an autolyzed yeast preparation. The hypochromic and erythroblastic anemias both responded to large doses of iron. Many aspects of metabolism were found to be abnormal. The blood sugar curves after dextrose were much flatter than normal. Similarly the blood urea was often below normal. In thirteen of the fifteen patients the serum calcium was low, and the plasma phosphorus was low or normal in ten and above the limits of normal in the remaining five. The height of the plasma phosphatase coincided approximately with the degree of active changes in the bones. Calcium balance estimations showed high figures for fecal output and low figures for urinary output. The authors suggest that this clinical picture is dependent on a disturbance of gastro-intestinal function resulting in deficient production, absorption or utilization of one or more essential factors.

- *Residual Chromic Index: New Test of Glycolytic Insufficiency. M. Polonovski and H. Waremberg.—p. 793.
Tuberculous Inflammation of Superior Right Lobe of Lung. G. Poix and H. Denecheau.—p. 796.
Treatment of Typhoid by Neoparsphenamine. H. Wohlers and R. Audéoud.—p. 799.

Test of Glycolytic Insufficiency.—Polonovski and Waremberg's new test of glycolytic insufficiency consists in the indirect determination of the intermediate products of sugar metabolism in the blood plasma. The first step consists in the oxidation of the plasma with a sulphochromic solution and titration of the excess of chromic acid. The blood is drawn into sodium fluoride. The plasma proteins are precipitated with tungstic acid. To 2 cc. of the filtrate is added a known quantity of sulphochromic solution of tenth normal dichromate with 25 per cent of sulphuric acid, and the mixture is kept in a boiling hot water bath for one hour. The excess of dichromate is determined iodometrically by titrating with twentieth normal sodium thiosulphate in the presence of starch. The quantity of tenth normal dichromate necessary for the oxidation of 1 cc. of deproteinized plasma is called the total chromic index. After the chromic index of sugar has been computed from the molecular formula and a quantitative determination of the sugar content of the plasma has been made, the amount of dichromate utilized by the sugar in the plasma can be calculated; this is termed the chromic index of dextrose. The difference between it and the total chromic index constitutes the residual chromic index. In the normal fasting adult the residual chromic index varies between 0.30 and 0.60. As the nonprotein nitrogenous constituents of the plasma account at most for 50 per cent of the normal residual chromic index and the other constituents utilize only a negligible fraction of the dichromate, the residual chromic index represents primarily the intermediate products of sugar metabolism. In a general way, the physiologic variations of the residual chromic index are parallel to glycemia. In all cases in which a disturbance of sugar metabolism exists, whether it concerns diabetes, hepatic insufficiency, obesity, hypertension, exophthalmic goiter, cardiac insufficiency, the active period of infectious diseases, a postoperative syndrome, pregnancy or cancer, an abnormally elevated residual chromic index is found. These facts and the constant correspondence observed between the elevation of the residual chromic index and the increase of an artificially induced hyperglycemia justify the determination of the residual chromic index as a test of glycolytic insufficiency. An elevated residual chromic index is one of the first signs of glycolytic insufficiency. Further, serial determinations of this index may give useful indications for prognosis and therapy. The test is made more sensitive by determination of the index before and three quarters of an hour after ingestion of 100 Gm. of dextrose. Any residual chromic index exceeding 0.60 and any elevation of that index three quarters of an hour after ingestion of 100 Gm. of dextrose shows a disturbance of the sugar metabolism. The only exception to this is found in cases presenting uremic retention of more than 0.8 Gm. in a liter; in such cases the increase of the residual chromic index may be independent of the disturbances of sugar metabolism and does not permit any conclusions on this point.

*Treatment of Meniscal Lesions of Knee: Enlarged Incision of Barker Considered as Best Access to Intra-Articular Fibrocartilage. J. Stefanini.—p. 349.
Architecture of Cranium: Its Functional Role and Mode of Resistance. Gallois, Japiot and A. Levy.—p. 371.

Treatment of Lesions of Knee.—Stefanini thinks that the only treatment for traumatic lesions of the semilunar cartilage is total excision of the cartilage concerned and that the only route of access to be taken into consideration is transverse arthrotomy. After describing and critically evaluating several methods that make use of transverse arthrotomy, he describes Bonnet's modification of Barker's method, which he thinks meets all the requirements for a satisfactory intervention. It easily permits total removal of the meniscus without mutilation disproportionate to the lesion to be treated, while it preserves

the integrity of the lateral ligament. The first step consists in locating the interarticular line between the bones, perceptible when the knee is flexed, the lateral condyloid tubercle and the direction of the lateral ligament, the internal noticeably vertical and the external slightly oblique below and behind toward the head of the fibula. An incision is made in the form of a J, starting the lower branch, with its concavity upward, at the level of the lateral ligament and continuing it forward by its vertical branch which rises parallel to the patella, about 0.5 cm. from the lateral margin up to two or three fingerbreadths below the base of the patella. The incision must be made higher to permit inward luxation of the patella to reach the external meniscus than for outward luxation of the patella to reach the internal meniscus. A puncture is made with a bistoury and the articulation and the quadricipital pouch are opened with scissors cutting at one time the synovial membrane, the plicae alares and the fibers of the vastus, and, in the lower part, keeping below the meniscus and following at the level of the interarticular line the arc described by the lower branch of the skin incision. With the leg flexed against the thigh, the patella is dislocated toward the side opposite the incision. When the leg is in maximum flexion the entire intercondylar region is exposed and, with the aid of small movements of torsion and adduction or abduction, the injured cartilage is easily detached from one end to the other. The synovial membrane and the fibromuscular planes may be sutured separately or together. The joint is immobilized with a Boeckel splint for a week until removal of the sutures. Active elevation of the leg in extension is started the day after the intervention to limit the atrophy of the quadriceps. By this modification of Barker's method, total removal of the meniscus can be performed more easily and rapidly than by any other route, the articular stiffness and muscular atrophy are reduced and the risk of future articular weakness is avoided. Absolute restoration of function was obtained in the seven cases in which operation was performed in this way by the author.

Bronze Diabetes.—Bufano states that bronze diabetes is a partial secondary symptom of the primary disease, hemochromatosis. Nothing is known of its etiology. It may be brought on by imminent malaria, alcoholism and chronic gastrointestinal disturbances. It is found exclusively in men, which, according to the author, suggests the possibility of disturbances of the internal genital function. The anatomopathologic lesions consist of large deposits of hemosiderin in the cellular elements of almost all the organs, with predilection for the liver. According to most authors, the pathogenesis of hemosiderosis consists of an inability of the organs and the cell systems, which normally dispose of the substances derived from the catabolism of hemoglobin, to consume the hemosiderin, which consequently is deposited in the parenchyma of almost all the organs and causes their degeneration. Following the primary lesions, many symptoms occur, depending on the organs involved and how seriously they are involved, among them being pancreatic diabetes, hepatic cirrhosis, hyposuprarenalism, disturbances of the myocardial function, various endocrine syndromes, and cutaneous melanosis of mixed origin (hyposuprarenalism and hemosiderosis). The prognosis is fatal. In cases in which it is not possible to make the diagnosis because of the suspicion that the cutaneous melanosis is not due to hyposuprarenalism only, it is considered best to resort to cutaneous biopsy. The author describes a case with histologic alterations of the liver, pancreas, suprarenals, spleen and skin. Hemochromatosis was established. The presence of a deficiency in the testicular function probably influenced the development of the hemochromatosis. It is still doubtful whether the disease is due to the inability of the organs to consume the derivatives of the hemoglobin and not to a fixation of the hemosiderin in the parenchyma.

Treatment of Prostatic Hypertrophy.—Wladika reports the experiences of the past fourteen years (with the treatment of prostatic hypertrophy) in the clinic of Rubritius in Vienna. Of 448 patients with prostatic hypertrophy, 351 were operated on. The greatest age incidence was in the seventh decade. Of these, 188 patients were treated before admission to the clinic by permanent catheterization, bladder irrigation and self catheterization, presumably because of fear of prostatectomy on the part of the general practitioner. High blood pressure is apparently not caused by the urinary retention because the removal of the condition did not have the effect of lowering it. Cystoscopy was not practiced in the clinic as a routine, because of fear of lighting up an infection and because it is in most instances superfluous. Neurologic examination is capable of excluding spinal cord bladders, while cystography will reveal calculi and, above all, diverticula. Associated calculi were present in 16 per cent of the cases. The author points out the futility of incomplete operation; that is, of the removal of stones while ignoring the existence of prostatic hypertrophy. Recurrence of stones takes place because of continued urinary stasis and infection. Attention is called to frequent development of inguinal hernias, at times bilateral, and to the futility of operating on these before the main cause, the difficulty in micturition, has been removed. The most reliable test of renal function is the water concentration test of Koeany. It takes into account both water excretion and water concentration. Satisfactory function implies the ability to excrete not less than 70 per cent of the imbibed fluid after four hours. They have not had a single instance of postoperative uremia since adhering to this test. The indigo carmine test is easily executed but is not as reliable. Diabetes did not constitute a contraindication to operation. The author considers the suprapubic transvesical enucleation of the prostatic adenoma the operation of choice. Epidural anesthesia proved most satisfactory. Postoperative bleeding was prevented by careful hemostasis accomplished by ligation of blood vessels after the enucleation. Tamponade was seldom resorted to, because of its tendency to cause local necroses and to prolong convalescence. Ligation of vasa deferentia at the time of prostatectomy or of primary cystotomy prevents the complication of postoperative epididymitis.

Acute Dilatation of Stomach.—Von Szacsvey calls attention to the fact that the analysis of the histories of patients suffering from acute dilatation of the stomach of other than postoperative or traumatic type reveals that ingestion of unusually large quantities of raw indigestible vegetables was the cause in every instance. The author argues that overloading the stomach alone is not sufficient, otherwise the condition would be much more common. Other factors, possibly such as cause a disturbance in the innervation of the stomach wall, are required. Analysis of the histories of these patients reveals the existence of an infectious disease, of a toxemia, or of chronic poisoning. In the author's case, the eating of sausage, probably tainted, had first given rise to symptoms of discomfort in the epigastric region. To relieve this discomfort the patient ate a large quantity of kraut. The elaboration of toxic products, the hypersecretion and the formation of gas affected

the innervation of the gastric wall, which in turn gave rise to atony, dilatation and complete paralysis of the stomach. The patient was submitted to a laparotomy because of an erroneous diagnosis of intestinal obstruction. Attention is called to the fact that a plain flat roentgenogram is capable of furnishing sufficient information, which should enable one to avoid this error.

Differential Diagnosis of Weil's Disease.—According to Schottmüller it is not entirely correct to consider Weil's disease (infectious jaundice) a rare occurrence, for in addition to the typical cases with their sudden onset with fever, chills, jaundice, hemorrhagic nephritis and pains in the calves of the legs and in the joints there are also atypical forms in which even the most characteristic of the symptoms, jaundice, may be lacking. This explains why some cases are not recognized. Until it was possible to demonstrate the pathogenic organism, *Leptospira icterohaemorrhagiae*, in the blood or the antibodies in the serum, the diagnosis was always difficult and unreliable. The author points out that infectious jaundice is a constitutional disease, because the leptospiras find their way into the blood; but, in view of the fact that a septic focus is not demonstrable, he considers it incorrect to call the disease a septicemia. Nevertheless, there are certain similarities between bacterial sepsis and Weil's disease, because a more or less pronounced jaundice develops in many cases of septic endocarditis, puerperal sepsis and osteomyelitis. The fact that these forms of sepsis occur sporadically is, however, no differentiating factor from the usually endemic Weil's disease, for the latter may also develop sporadically. The bacteriologic tests are sometimes the only means of differentiating between sepsis and Weil's disease. The differential diagnosis is especially difficult in disorders in which the septic focus is in the region of the liver, such as in pyelophlebitis, in cholangitides that develop following achylia gastrica and in typhoidal and paratyphoidal cholangitides. The differentiation nearly always necessitates a serologic or bacteriologic examination. Cases of gas bacillus sepsis, which the author observed as puerperal infections, also frequently exhibit symptoms of Weil's disease. An erroneous diagnosis is especially likely if the abortion has already taken its course and the patient does not reveal it. The presence of hematin in the serum and of the disintegration products of hemoglobin in the urine favors gas bacillus infection, and the bacteriologic examination generally clears the etiology entirely. Gas bacillus infection of the gallbladder is even more difficult to differentiate than are the aforementioned gas bacillus infections. The author cites a case in which the diagnosis was not established until the bacilli were detected in the extirpated gallbladder. Blackwater fever may eventually be confounded with Weil's disease. The condition that is most readily and most frequently confounded with Weil's disease is icterus catarrhalis, but this disorder as well as the form of jaundice developing in the course of scarlet fever can likewise be differentiated by bacteriologic tests. The author considers a blood transfusion of 1 liter from a convalescent donor the only effective treatment for Weil's disease.

Paralysis of Extensors in Lead Workers.—Teleky gives the clinical histories of three patients who, after working with lead, developed paralysis of the extensors of the arms and hands. The exposure to lead poisoning was comparatively slight. This and the fact that the paralysis developed suddenly and disappeared again in a comparatively short time seem to indicate that lead poisoning cannot have been the only pathogenic factor. That the paralysis developed in those muscles which had been greatly exerted seems to indicate that the

paralysis was the result of the concerted action of the exertion and the lead poisoning. Moreover, in two of the patients the involved muscles seemed to be weak, but the author does not deny the possibility that lead may have an elective action on the affected extensor muscles.

Effects of Serum Therapy in Peritonitis.—Gundel and Süssbrich present the results of their investigations on the efficiency of serum therapy in peritonitis of various types. The predominant form was that resulting from perforation of an inflamed appendix. The serum treatment was controlled by and based on the bacteriologic studies of the pus from the peritoneal cavity. In addition to the polyvalent serums, the authors investigated the effect of various combinations of antitoxic serums in thirty-six patients. An idea as to the greatest antibody content of any given serum was obtained from control bacteriologic studies. The Bacillus coli antitoxic serum proved to be of considerable importance, since their bacteriologic studies demonstrated the prevalence of *B. coli* in peritoneal infections. There remained a considerable proportion of patients in whom the enterococcus of type B and the various related transitional forms of the strepto-enterococcus group, as well as the gas bacilli, played the leading part. The authors point out that the etiologic significance of the latter must not be underestimated because, on the one hand, they were able to obtain the enterococcus in pure culture in several instances and, on the other, they were able to demonstrate the morbid effect of the absorption of gas bacilli. It was found that of the several combinations that of *B. coli* serum with gas bacillus serum and the enterococcus serum was the most effective. They prepared a serum containing approximately 65 per cent of the antitoxic *B. coli* serum, 25 per cent of the enterococcus serum and a potent gas bacillus antitoxin containing 100,000 Behring units in each 40 cc. of serum. In their opinion, a combination of this sort enlarges the scope of usefulness of a serum against peritonitis. Its use is rational not only in postappendicular peritonitis but in other forms as well, particularly in the form following perforation of a gastric ulcer.

Recurrence of Inguinal Hernia.—Ostfeld made a follow-up study of 239 patients operated on for inguinal hernia. The Bassini operation without any modification was employed. The suture material consisted principally of silk. Suppuration occurred in 3 per cent, hematoma in 2.4 per cent, scrotal edema in 0.9 per cent, and postoperative pulmonary complications in 12 per cent of the patients. In a total of 586 patients operated on for inguinal hernia, local anesthesia was used in 445, ether in 115, nitrous oxide gas in 12, tribrom-ethanol in 3, and epidural anesthesia in 1. The incidence of recurrence was 5.4 per cent. If operations by beginners were to be excluded, this figure could be lowered to 1.6 per cent. The following observations were made with regard to the causes of recurrence: Disturbances in the course of convalescence were present in 12.2 per cent of the recurrences. Too early resumption of heavy work was responsible for 15.8 per cent. The wearing of a truss for a long period had an unfavorable influence on the sterile condition of the wound as well as on the question of recurrence. The effect of early getting out of bed was not apparent, as the author did not notice any untoward effect from letting the patients get out of bed on the sixth postoperative day. The number of recurrences in persons doing heavy labor was ten times as great as that in persons doing light labor. The effect on recurrence of a chronic cough, of parturition, of appendectomy and of indulgence in sport was uncertain. To obviate

the bad effects of wearing a truss, the author recommends that all hernia carriers between the ages of 5 and 60 years be operated on, provided some special contraindication is not present. The influence of a hereditary predisposition to hernia on recurrence was unmistakable. It was present in two thirds of the recurrences. He suggests that patients stigmatized by a hereditary tendency to hernia formation abstain from heavy work and physical exercise for longer periods of time than is customary. The author considers the original Bassini still the most useful operation for inguinal hernia.

- Clinical Aspects of Still's Disease and of Chronic Arthritis in Infants. H. Ahle.—p. 57.

Experimental Exsiccosis.—Csapó and Kerpel-Fronius produced exsiccosis in young dogs (10 days old) by means of a diet with high protein content and by low water intake. It was found that the freezing point of the blood serum was considerably lowered, which indicates azotemia and an increase in the sodium chloride content. The authors designate this condition of the blood as hypersalemia. The bicarbonate is only slightly reduced; the reduction is a result of an increase in the organic acids. In spite of the great increase in the chlorine, the acidosis is not a chloracidosis, because the increased chlorine content is compensated by an increase in bases. The changes in the blood are the result of a disparity between intake and elimination; they are primarily the result of retention. The water deficiency, the osmotic disturbance and the changes in the ional milieu lead to severe metabolic disturbances, which together cause the breakdown of the organism.

Pathogenesis of Acetonemic Vomiting.—Weichsel shows that the assumption that acetonemic vomiting is a metabolic disturbance was refuted by Salomonsen, who proved that a ketogenic diet does not produce vomiting during the attack-free interval. Others, particularly Heymann, contradict Salomonsen and maintain that acetonemic vomiting is the result of a metabolic disturbance in the intermediate metabolism of the liver in children with a neuropathic constitution. In repeating Heymann's tests during the attack-free intervals on four children who were subject to acetonemic vomiting, the author found that the children always developed ketonuria but never a typical attack of acetonemic vomiting. Accordingly, he agrees with Salomonsen and rejects the metabolic disturbance as the primary causal factor of acetonemic vomiting.

Treatment of Epidemic Cerebrospinal Meningitis.—Of twelve children with epidemic meningitis, Nuske treated five by endolumbar or intramuscular injection of serum, and seven by withdrawing spinal fluid and introducing air. The withdrawal was done generally with the child in the recumbent position and by means of a needle introduced into the lumbar region of the spinal cord. With the aid of a rubber tube connecting needle and syringe, disarrangement was prevented during interruption of the withdrawal, for the 20 cc. syringe had to be taken off and emptied when it was filled, and then the same amount of air was introduced while the child was in the sitting position. If the discharge of fluid was slight, withdrawal was done in the sitting position, and if the discharge remained slight, a suboccipital puncture was made. If the discharge was satisfactory from the beginning, air was not introduced until the pressure became lessened. The air volume was nearly always smaller than the fluid volume. Of the five children who were treated with serum and with symptomatic remedies only two recovered, while of the seven treated by withdrawal of fluid and by air inflation four recovered. The author points out that the three fatalities of the last group are not necessarily due to the failure of the inflation treatment but may perhaps be accounted for by the fact that the treatment

was commenced too late or was not carried out adequately. The success of the treatment in the other four cases is the result of the early beginning and of the daily application of the treatment. In spite of the small number of cases, the author gained the impression that serotherapy of epidemic meningitis is not more effective than fluid withdrawal and inflation and he thinks that its efficacy may even be partly due to the latter. At any rate, he states that withdrawal and inflation deserve a trial, the more so since observations so far have proved them harmless.

Number of Uterine Contractions and Obstetric Interventions.—In 490 carefully observed deliveries, Winter determined whether Walthard and Frey were correct in their statement that the necessity of an obstetric intervention can be determined on the basis of the number of uterine contractions and he concedes that Frey's observations are generally correct. His estimates of the highest number of uterine contractions for primiparas and multiparas, for women with narrow and normal pelvis and for those with normal and with premature rupture of the bag of waters tally with those of Frey, but he emphasizes that the decision on the advisability of an obstetric intervention should not be based exclusively on the highest number of uterine contractions, because other factors should be considered.

Influence of Athletics on Menstruation.—Hoffmann made her observations on eighty-seven students of a training school for teachers of athletics and on 127 students receiving training as laboratory technicians, photographers or metallographers. In the training school for teachers of athletics, from twelve to eighteen hours was devoted each week to various forms of gymnastics and approximately the same number of hours to attendance at lectures (pedagogy, psychology, anatomy, hygiene and so on). The girls being trained for technical occupations devoted from forty to forty-two hours to theoretical and practical work. Approximately one third of the latter group took some form of gymnastic exercise twice a week or more. The author gives tabular reports of the two groups of students indicating the constitutional types, the age at the time of the menarche, the length of the menstrual cycle, the duration and quantity of the discharge, the complaints and the efficiency during the menstrual period. A comparison of the course of menstruation in the two groups of girls before the beginning of the occupational training indicates that the students of the training school for teachers of athletics were of a better physical type than those being trained for the technical occupations, for only 5.6 per cent of the first group had irregularities in the cycle, whereas in the second group the percentage was 15.7. The percentage of those being entirely free from complaints was even more striking, being 74.7 for the students receiving training as teachers of athletics, while it was only 34.6 for the other students. However, in the course of the occupational training this picture changed. Of the students being trained for technical occupations, only a few developed changes in the menstruation, the irregularities in the cycle predominating (five cases). In four the cyclic irregularities developed in connection with the occupational training and in one following gymnastic activity. Leukorrhea developed in three of the students, in two of them in connection with athletic activities. Special attention

was given to menstrual disturbances of the students who received training as x-ray technicians. Three of these students developed cyclic changes and two others had increased pain; but, since the other menstrual changes were not more frequent in these than in other students, the author does not consider it definitely established that the aforementioned changes were caused by the roentgen rays. Twenty-five of the students of the training school for teachers of athletics developed irregularities of the menstrual cycle. Interruptions up to nine weeks' duration developed particularly during intense athletic training, but these changes were temporary in most instances and the cycle became normal again after the intense training was discontinued, although the irregularities persisted for longer periods in eight students. On the other hand, there were six students in whom the menstrual period became more regular during attendance at the training school. Changes in the duration of the flow were observed in twenty-one students, and the quantity of the discharge changed in nine. Painful menstruation was reported by twenty-eight of the students, but only thirteen of these developed them as the result of the athletic training. On the other hand, there were eight students in whom the pains became lessened as the result of the gymnastic training. Leukorrhea developed in fourteen of the students. In evaluating the various changes, the author points out that they should not all be ascribed to the athletic activities, because environmental influences and changes in the sexual life should also be taken into account.

Operative Treatment of Congenital Umbilical Hernia.—After citing statistical reports that prove the rarity of congenital umbilical hernias (one case in 6,600 births), Ludwig describes three cases observed by him. All three received surgical treatment and two infants recovered. The author considers the conservative treatment of congenital umbilical hernias by means of alcohol compresses advisable only in those cases in which infection and necrosis have already set in and in which peritonitis could no longer be prevented by a surgical intervention. Whenever possible, congenital umbilical hernia should be given surgical treatment, for the earlier the operation is performed, the more favorable the prognosis. It is best to receive the child at birth into a sterile cloth and perform the operation immediately.

*Can Pneumoperitoneum Be Employed in Collapse Therapy of Bilateral Pulmonary Tuberculosis? L. Vajda.—p. 371.

Malignant Tumors Simulating Tuberculosis.—Nicol shows that the early diagnosis of intrathoracic tumors and their differentiation from tuberculosis is often difficult. The primary tumor, by exerting pressure on the vagus nerve, frequently produces symptoms of irritation, such as a dry cough, manifestations characteristic of chronic relapsing bronchitis and slight hemoptysis. The sedimentation speed of the erythrocytes is often considerably accelerated. Deviation to the left concurring with lymphocytosis favors the diagnosis of tumor rather than of tuberculosis. If the tumor grows, fever may develop and there are pains radiating to the back and the pelvis if the pleura is involved. An increasing dyspnea that cannot be explained by other causes and paroxysmal, pertussis-like attacks of coughing should always direct the attention to the possibility of a tumor; and manifestations of bronchostenosis, atelectasis, dilatations of the cutaneous veins on the diseased side of the thorax and edemas are still more demonstrative in that direction. Laryngeal symptoms deserve especial consideration. Hoarseness is not only an early sign of pulmonary tuberculosis but also an early symptom of tumor and, in case of paralysis of the vocal cords or of the recurrent laryngeal nerve, the possibility of a tumor should be considered. An exudative pleurisy is not necessarily a sure sign of tuberculosis, for a

pleuritic exudate, particularly a hemorrhagic one, quite frequently masks a beginning tumor. The signs of pulmonary tumor detectable by physical methods are generally slight. Larger tumors may produce dullness which, because of the absence of auscultatory manifestations, is referred to as "mute." The endotheliomas of the pleura generally present the aspects of chronic adhesive pleurisy. Roentgenoscopy is the most important method in the detection of intrathoracic tumors. A broadening of the hilus shadow, a wedge-shaped protrusion of the shadow into the pulmonary fields, sharp demarcation of the shadow on the margins of the lobes, widening of the upper mediastinal shadow with arched demarcations that reach into the pulmonary outlines, and the rapid development of the shadows to diffuse forms in frequently repeated roentgenoscopy indicate tumor rather than tuberculosis. Diagnostic pneumothorax is helpful in many instances, particularly in exudative pleurisy after the exudate has been withdrawn. Thoracoscopy frequently aids in the detection of pleural tumors. Differentiation between pulmonary sarcomas and carcinomas is difficult, but primary sarcomas of the lung are much less frequent than carcinomas, and sarcomas grow much more rapidly than carcinomas. The problem whether malignant granuloma is directly related to tuberculosis, that is, whether it is caused by a tuberculous virus, has not been decided as yet. Its differentiation from tuberculosis is difficult, but frequent examination of the sputum with negative outcome, the undulating course of the remittent fever, and the development of glandular metastases will generally lead to a correct diagnosis. The author points out that tumor and tuberculosis may exist simultaneously. In these cases the tuberculosis generally antedates the tumor, but the development of the tumor generally has no effect on the course of the tuberculosis.

Sensitivity of Skin of Tuberculous Patients to Iodine and Histamine.—Intracutaneous tests with iodine and with histamine solutions convinced Lass that patients with tuberculosis are hypersusceptible to these solutions. This hypersusceptibility becomes manifest in a more or less intense reddishness around the wheal and in a retarded resorption of the wheal. In normal persons these manifestations are extremely rare. The severity of the disease frequently runs parallel with an increase in the histamine susceptibility and with a relative decrease in the iodine susceptibility. Early tuberculosis and cases with a favorable prognosis frequently show more intense iodine than histamine reactions. The cause of this parallel behavior of the skin and the pulmonary tissues is unknown, but the author suggests that the connection may be found in the changed reactivity of the sympathetic nervous system. At any rate, the sympathetic status seems to influence the allergic condition. According to Unverricht, patients with a hypersensitive sympathetic nervous system react to tuberculous infection with a more marked inflammatory reaction, and Moro, who coined the term "nervous allergy," maintains that the intensity of the tuberculin reaction is dependent on the reactivity of the sympathetic nervous system. The author thinks that her observations on the reaction of the skin to intracutaneous injections of solutions of iodine and histamine in the various stages and forms of tuberculosis is of interest and, although she does not ascribe a specific character to the reactions, she nevertheless considers them more than mere traumatic cutaneous results.

Pneumoperitoneum for Collapse Therapy of Bilateral Pulmonary Tuberculosis.—Vajda thinks that the improvement of tuberculous processes, frequently observable during pregnancy, is partly the result of the upward movement of the diaphragm produced by pressure from below. He therefore tried to induce this condition artificially by means of pneumoperitoneum. He describes his observations on two patients. The first one was given 1,200 cc. of air and the second one 700 cc. Complications did not develop and the function of the abdominal organs was unimpaired. The diaphragms were forced upward to an extent possible only in an unusually successful phrenic exeresis, and their excursions were considerably limited, which is likewise a desirable component of collapse therapy. The author considers pneumoperitoneum advisable in prolonged pulmonary hemorrhages that cannot be influenced by internal measures and in which, if the process is bilateral, the bleeding side cannot be determined or in which a bilateral pneumo-

thorax is inadvisable on account of adhesions, and also in cases in which other surgical methods are not practical or have little prospect of success.

- Menstrual Cycle in Endometrial Heterotopias. J. J. Chydenius.—p. 211.
 *Blood Picture in Chronic Alcoholism. E. Lindström.—p. 225.
 *Case of Diffuse Tumor Formation in Soft Meningeal Membranes in Case of Cancer of Stomach. R. Gordin.—p. 245.

Blood Picture in Chronic Alcoholism.—The results of Lindström's examinations of the blood in fifty-two cases testify against the assumption that chronic abuse of alcohol plays a part in the origin of polyglobulism.

Diffuse Tumor Formation in Soft Meningeal Membranes in Cancer of Stomach.—In Gordin's case in a man, aged 29, the first diagnosis was toxic polyneuritis with psychic symptoms. As the grave anemia gradually dominated the picture, a primary disease of the blood (atypical pernicious anemia?) seemed probable. The symptoms from the spinal cord, marked subjective disturbance and areflexia, were attributed to secondary degeneration in the spinal cord, and the focal symptoms in the later stage to changes in the blood vessels. Enlargement of the supraclavicular and inguinal glands was the first indication of a malignant neof ormation in the organism. Necropsy revealed a diffuse infiltration of the gastric wall, found to be an aplastic cancer on histologic examination. Infiltration with tumor cells was seen in the lymph glands. The soft membranes of the brain and pia were diffusely infiltrated with tumor cells, which also infiltrated the spinal ganglions. The general fibrous thickening of the soft membranes of the spinal cord was most evident in the cervical region, and the degree of degeneration of the spinal cord most extensive in the lumbar and cervical regions. The author cites from the literature sixteen cases with diffuse infiltration of the soft meninges in connection with cancer of the stomach in which anatomohistologic examinations were made. The metastases in his case are thought to have occurred along the perineural lymph tracts.

 Experimental Pellagra and Its Significance in Understanding of Etiology of Disease. S. Clemmensen.—p. 349.
 *Secondary Pellagra. Else and H. P. S. Teglbjærg.—p. 356.
 Enterocystomas: Casuistic Contribution; Review. K. Keitel.—p. 365.

Pellagra.—Thaysen's four cases show the varied picture in pellagra, from dermatitis as the only certain symptom in the first case to practically all the symptoms of a grave pellagra in the third and psychic symptoms dominating and causing death in the fourth. The pellagra was complicating or secondary in all cases, the primary disorder being a psychosis in one case and a gastro-intestinal disturbance in three. While the first two cases agree with Goldberger's theory, in the third the prognosis continued grave for a long time in spite of administration of abundant vitamin B₂, and in the fourth the pellagra occurred in spite of an adequate diet. Referring to the literature, the author discusses the possibility of an endogenous avitaminosis in certain cases. It seems to him probable that a disorder of the gastro-intestinal tract can cause pellagra by hindering resorption or utilization of the B₂ vitamin of the diet, or the increased vitamin requirement of the organism is not met by the amount ingested. As certain diagnosis still depends on the manifestation of dermatitis which usually occurs in the springtime, while the pellagra may set in at any season, the disease may remain unrecognized for several months, with delay in treatment and aggravation of prognosis.

Secondary Pellagra.—During the last six months the Teglbjærgs have found five cases of secondary pellagra in the psychiatric-neurologic "Colony Philadelphia," also three cases in journals of discharged patients. As the diet was not deficient in vitamins, the pellagra is ascribed to simultaneous or earlier intestinal disorders causing deficiency in vitamin resorption. The administration of abundant vitamin B₂ was effective in all cases in which it was used. Secondary pellagra is believed to be relatively frequent among patients who refuse to eat and in long continued gastro-intestinal cases. The neuroses

show a remarkable affinity to the sympathetic and extrapyramidal system, and in the psychoses the depression states predominate.

95: 513-542 (May 4) 1933

- *Idiosyncrasy to Flour as Cause of Vasomotor Rhinitis and Asthma. K. Baagø.—p. 513.
 *Unusual Occurrence of Familial Goiter. C. Clemmensen and G. E. Schrøder.—p. 520.
 Pericarditis in Sylvest-Bing's Disease. T. Dalsgaard-Nielsen.—p. 522.

Idiosyncrasy to Flour.—Baagø finds among bakers an apparently frequent occupational disease due to inhalation of flour dust. The disturbance may be grave enough to force a change of occupation and is as a rule only unpleasant for the patient and highly unhygienic. Seventeen cases are reported.

Familial Goiter.—Clemmensen and Schrøder report eight cases of thyroid disorder in eight brothers and sisters, the children of apparently healthy parents. The four brothers had large goiters which developed at the ages of from 15 to 18, three with symptoms of pressure and nervous symptoms leading to excision in two. Of the sisters, three had small goiters; the fourth, marked myxedema with dwarfism and imbecility. These cases seem to indicate that heredity can follow hitherto unknown laws or that wholly unknown factors are active.

 Investigations on Blood Content of Atoxyl-Resistant Lipases (Pancreatic Lipases) in Normal Pregnant Women. K. Germier.—p. 553.

Spontaneous Hypoglycemia.—Gram says that hypoglycemia may be caused by various changes in endocrine organs other than the islands of Langerhans and may be observed without certain anatomopathologic explanation; spontaneous hypoglycemia occurs in benign and malignant tumors originating from the insular tissue of the pancreas. The symptoms correspond closely to those of insulin intoxication and usually appear periodically, with predilection for the morning and longer intervals between meals. Ingestion of food can often ward off an attack. The blood pressure during the attack is low. Treatment consists of frequent meals with abundant carbohydrates for milder attacks, and infusion of isotonic solution of dextrose, possibly also injection of epinephrine, in graver attacks. In grave cases in which laparotomy fails to reveal a tumor in the pancreas, partial resection of the gland may be attempted, although the optimal fraction is hard to determine.

Xanthomatosis, Dyspituitarism, Christian's Syndrome.—Svenningsen's case of general xanthomatosis in a girl aged 4 has shown progressive development of the different symptoms during the past year. The prognosis in this disease seems to him desolate, the only possible ray of hope lying in roentgen treatment.

AN APPRAISAL OF ANTIRACHITICS IN TERMS OF RAT AND CLINI- CAL UNITS

ALFRED F. HESS, M.D.

AND

J. M. LEWIS, M.D.

NEW YORK

It has become increasingly evident that there are now available a considerable number of valuable, indeed almost specific, agents for the prevention of rickets. This fact needs no additional confirmation except in detail. There are, in all, five reliable and well established antirachitics, each one of which represents a distinct and different pharmacologic point of view. The first to be established was cod liver oil, a natural product; the second to be introduced was direct irradiation of the body by means of ultraviolet energy; the third was irradiated food, particularly milk, activated by exposure to ultraviolet radiations; the fourth, an irradiated basic substance, ergosterol, extracted from yeast; the fifth, representing still another method, was "yeast milk," a biologic product endowed with antirachitic potency as the result of feeding irradiated yeast to the cow. In addition to these five established agents there are numerous others which consist of various modifications or combinations; for example, the addition of a concentrate of cod liver oil to milk, or of viosterol to cod liver oil. Whether one or the other of these several antirachitics should be adopted in the campaign to eradicate rickets from the community will depend not so much on their efficacy in preventing rickets as on their availability, which involves their cost to the consumer, the readiness with which they are accepted by the public, their palatability and other nonmedical considerations.

It is now eight years since it was demonstrated that milk can be rendered highly antirachitic by a short exposure to ultraviolet radiations.¹ The method has been remarkably slow of adoption in this country, owing largely to the necessary delay incidental to evolving a satisfactory technic. For some years a commercial preparation of dry milk has been activated in this way, but this winter for the first time irradiated fluid milk was marketed on a large scale in one of the large cities (Detroit). For the past two winters clinical tests have been carried out in the clinics of the department of health of New York City and it was established unequivocally that irradiated milk is able to

prevent rickets, indeed even in the Negro infant.² In regard to the latest addition to the fold, "yeast milk," clinical experience in New York³ and in Boston⁴ has established the reliability of this interesting method of elaborating a specific food.

Some three years ago it was shown that the assumption that the potency of one antirachitic can be expressed interchangeably in terms of another does not accord with clinical experience.⁵ For example, many more "rat units" of viosterol than of cod liver oil were found necessary to protect or to cure infants. On the basis of standard bio-assays they were by no means interchangeable. In the following year it was shown that a similar inconsistency held true in regard to other antirachitic agents and that irradiated milk required a surprisingly small number of rat units, as few as from 35 to 40 being sufficient to protect infants, as judged by the clinical observations of a large series of cases. Recently, Stokes and his colleagues⁶ have come to a similar conclusion.

These observations as to the lack of conformity in the clinic of various antirachitic agents gain additional support from experiments on rickets in animals. Some years ago it was shown that, in order to protect chickens from leg weakness, it was necessary to give them a far larger number of antirachitic units in the form of irradiated ergosterol than of cod liver oil.⁷ Massengale and Nussmeier⁸ came to the conclusion that 100 or even 200 times as much of the former might be required. Two years ago, in the course of an experiment devised to ascertain whether it was preferable to feed cows irradiated ergosterol or irradiated yeast in order to render their milk highly antirachitic, it was found that three times as many units of the former had to be incorporated in the daily ration in order to produce a milk containing 160 rat units to the quart; 30,000 rat units of irradiated yeast was equivalent to approximately 100,000 units of irradiated ergosterol and 60,000 to 200,000 units.³ These conclusions

are similar to those of Krauss and his colleagues,⁹ who found that the vitamin D in cod liver oil is more efficacious for calcification of the bones of chicks than that contained in the butter-fat from cows fed irradiated ergosterol.

The problem in regard to the various antirachitics is therefore not so much one of efficacy as of ascertaining the number of units required of each preparation in order to prevent or to cure infantile rickets. This question is fraught necessarily with interesting theoretical and practical implications. In the first place, it implies that the established method of gaging the value and potency of antirachitics is not only unreliable but misleading as well. To state that an antirachitic preparation contains 50 units might indicate, in the one instance, that it possesses adequate antirachitic protective power, or, in the other, that it is wholly inadequate and that the therapeutic dose should be increased many fold. From a laboratory point of view such discrepancies in the clinical value of various antirachitics implied that the regulations for measuring potency would have to be revised and that the newer "international units" could be accepted only with definite reservations. For example, although it would be quite in order to compare a sample of cod liver oil with the "reference" cod liver oil and of viosterol with the standard irradiated ergosterol, it would be highly misleading, from a therapeutic point of view, to compare the number of units of viosterol with that in cod liver oil. In view of the importance and timeliness of this problem it was decided to carry out another clinical investigation, introducing certain modifications.

In the first place, although we are interested in these therapeutic agents mainly from the point of view of the prevention of rickets, it was deemed advisable to carry out a curative rather than a protective clinical assay. Several considerations led us to take this point of view. In the first place it enabled the use of an objective clinical criterion, the roentgenologic picture, rather than a set of subjective criteria. A study based on roentgenologic healing of the epiphyses is necessarily more convincing than one based on mere prevention. This is all the more true of rickets, as there are marked inherent difficulties associated with the interpretation of its subjective signs, for example, of beading of the ribs, which is at times difficult to interpret. Again, craniotabes, the softening of parietal areas of the cranial vault, cannot be regularly prevented by any of the antirachitic agents even when given in the full therapeutic dose. Such has been our experience and, we believe, the experience of other clinicians; it may even diminish simultaneously with the development of roentgenologic lesions or make its appearance while the epiphyses are showing evidences of healing. Nor can one rely on the concentration of the inorganic phosphorus of the blood in judging whether or not the antirachitic agent has conferred protection. As pointed out from time to time, the inorganic phosphorus may remain at the normal level, especially in infants under 3 or 4 months of age, in spite of the fact that rachitic changes become evident in the epiphyses. In order, therefore, to remove uncertainties it was decided to carry out a curative test of a series of antirachitics and to make roentgenologic healing the criterion of potency. This decision was made with the realization that roent-

genologic rickets represents a moderate rather than a mild stage of the disorder.

In regard to irradiated milk, the same procedure was followed both as to potency and as to method of elaboration. It was activated by means of carbon arcs, great care being exercised to provide uniformity in the amount and character of applied energy. The apparatus delivered over 5,000 quarts an hour and the milk was subjected to the rays for a period of sixteen seconds ("flash irradiation"). It was found that milk treated in this manner contained from 50 to 60 rat units per quart and that the unitage was remarkably con-

Healing Brought About by the Minimal Curative Dose of Various Antirachitic Agents

* Milk given for only twenty-four days.
† 40 drops per cubic centimeter.

stant. In the accompanying table, milk of this kind is rated at 56 units per quart or 42 units for 24 ounces, the amount which was fed daily in most cases to each infant. In some cases it will be noted that only 16 ounces a day was given; in other words, 28 rather than 42 rat units. A change was made in regard to the strength of the yeast milk; in our last investigation this milk contained 160 rat units per quart and was found to confer protection or to bring about healing in every instance. The milk that was used in the present test contained fewer units, as it was felt that 160 units was unnecessarily high. The potency of yeast milk can be regulated to a surprising degree by varying the number of rat units of activated yeast which is fed to the cow. Accordingly, cows were segregated into two groups and irradiated yeast was fed to

9. Krauss, W. E.; Bethke, R. M., and Monroe, C. F.: The Effect of Feeding Irradiated Ergosterol to Cows on the Vitamin D Content of Milk, *J. Nutrition* 5: 467 (Sept.) 1932.

the one in an amount sufficient to yield about 120 rat units per quart and to the other in an amount to yield only 80 rat units per quart. Repeated assays proved that this milk developed approximately the potencies that had been calculated; the more potent milk varied merely from 110 to 120 rat units and the weaker from 75 to 80 units. It was likewise found possible in this test to feed smaller quantities of yeast to the cows, as a preparation of brewers' yeast was available which contained 70 D units per gram instead of only 25 to 30 D units, which was the most potent preparation fed two years ago. Babies were given 24 ounces daily of these two strengths of yeast milk, so that one group received approximately 90 and the other 60 rat units a day. The cod liver oil contained from 37 to 40 rat units per gram, making it a 3 D preparation. On the basis of 4 cc. (3.2 Gm.) to the teaspoonful, the children getting this amount received about 130 rat units daily and those who were given one-half teaspoonful, about 65 rat units. A preparation of viosterol was used having a potency of about 80 rat units to the drop (250 D), calculating 40 drops to a cubic centimeter. Four drops were given daily; in other words, the infants received about 320 rat units daily. All antirachitic agents were assayed not only by the laboratory in which they had been prepared but by one or more other laboratories, in order that there should be no question as to the potency of the product. This procedure was considered especially desirable in view of the fact that the question has been raised not only as to whether biologic tests can be relied on but as to whether preparations that have been used for clinical studies contained a far greater or less number of rat units than was supposed. In our previous experiments, assays were not carried out on the identical preparation that was given the infants. Another improvement or refinement in technic was introduced. In every case the roentgenologic observation as to healing was made after a period of four weeks, so that the therapeutic tests were comparable in this respect. In similar studies the time factor has not been rigidly observed, the infants having been under observation for longer or shorter periods. As we know that when assaying antirachitic agents it is imperative to set a fixed limit to the test period, it was deemed highly desirable to observe a similar procedure in the clinic. Most of the infants attended clinics of the New York department of health and we are indebted to the commissioner for his cooperation in connection with this study. The babies were not only carefully examined in the clinic but followed up by a nurse in the home to make certain that instructions were carried out.

Surveying the results, which are abstracted in the accompanying table, one finds that they conform remarkably well with our clinical experiences of the past few years in which the preventive rather than the curative method was employed. A survey of the column which reproduces the degrees of healing will show that the series fed the larger amount of irradiated milk and the higher potency of yeast milk fall into a group in which the results were outstanding. This irradiated milk contained approximately 56 rat units to the quart or 42 units to the daily quota of 24 ounces, and the yeast milk 120 units to the quart, or 90 to the 24 ounce quota. The "efficacy ratio" of the one milk to the other was almost two to one, the irradiated milk requiring about half as many units to bring about similar degrees of healing. The next best group is composed of irradiated milk given in only 16 ounce

amounts daily, of yeast milk of 80 instead of 120 unit potency. From the standpoint of unitage, the least potent of all was viosterol, which assayed at about 80 rat units per drop and of which 4 drops were given daily. In this series we gave, in terms of rat units, approximately 28 units of irradiated milk, 60 of yeast milk and 320 of viosterol. It is very striking that it was necessary to give such a large number of units of viosterol. The "efficacy ratio" of irradiated milk to viosterol has been found to be close to 15:1, about fifteen times as many units of activated ergosterol being required as of activated milk.

These results must be judged not only by themselves but in the light of similar investigations of the past few years, more particularly those undertaken in 1931 and 1932. During the winter of these years, extensive prophylactic as well as curative clinical tests were carried out with irradiated milk and with yeast milk. After a careful review of these various clinical studies we have come to the conclusion that an irradiated milk which contains approximately 56 units to the quart suffices to protect infants against rickets when from 20 to 24 ounces daily is fed, which indicates that the protective dose is about 35 to 42 rat units. A similar survey of our clinical experiences with yeast milk leads to the conclusion that this type of milk should be elaborated so as to contain 100 or possibly 90 units per quart, so that the infant will receive about 70 rat units a day. Turning to viosterol, our experience was not so satisfactory and we do not feel that we can set down the dosage with the same degree of definition. However, irradiated ergosterol in one strength or another has been given in our institution every winter since it was discovered, so that we have a large number of observations which cover a considerable period. On analyzing all these data and weighing them in conjunction with the present curative test, it would seem that about 600 to 800 rat units of this antirachitic agent should be given in order to afford adequate protection; this means from 8 to 10 drops of a 80 unit preparation (250 D). It will be seen that this dosage conforms with that usually recommended by physicians as well as by pharmacologists. As has been previously emphasized, viosterol given in adequate dosage is the most satisfactory antirachitic for curative purposes.

The study included a clinical appraisal of cod liver oil in $\frac{1}{2}$ teaspoonful (2 cc.) and 1 teaspoonful (4 cc.) amounts. The results were somewhat irregular and unsatisfactory. In regard to this antirachitic it is necessary, therefore, to fortify our observations by previous experiences as well as by the large number of reports in the literature. The preparation of cod liver oil which we assayed clinically this year, when titrated biologically in two laboratories, was found to contain from 37 to 40 rat units per gram. Dr. Nelson¹⁰ of the U. S. Bureau of Chemistry states that he has found a composite of twenty-six samples of medicinal cod liver oil to contain 37 Steenbock units per gram, so that the sample which we used may be regarded as representative. Indeed, judging by a paper of Drummond and Hilditch¹¹ and a more recent report of Coward,¹² from 37 to 40 rat units is representative of medicinal cod liver oil not only in this country but in England as well. In summing up our experience and the experiences of others with an oil of this potency.

10. Nelson: Personal communication to the authors.

11. Drummond, J. C., and Hilditch, T. P.: The Relative Value of Cod Liver Oil from Various Sources, H. M. Stationery Office, 1930.

12. Coward, K. H.: Analyst, June, 1932.

which is almost three times the standard, or about 3 D, it would seem that about 2 teaspoonfuls, or 8 cc., may be set down as the prophylactic dose. Translating cubic centimeters of oil into grams, the requirement becomes 6.4 Gm. daily, or about 250 rat units of cod liver oil. Although this figure is necessarily inexact, it is evident that, from the standpoint of effective unitage, the therapeutic dose of cod liver oil falls between the antirachitic milks and viosterol. This conclusion is in accordance with our previous experiences.

It is true that there is considerable variation in susceptibility to rickets and in individual requirement of the antirachitic factor. Only recently, in an experimental study, the rôle of constitution in the development of this disorder was stressed.¹³ Nevertheless, and in spite of such individual variations, the clinical course of rickets is sufficiently constant to justify the laying down of a definite dosage for the various antirachitic agents.¹⁴

It may be added, without entering minutely into the question, that the relatively high potency of irradiated milk and low potency of viosterol cannot be accounted for by the relative amounts of the antirachitic factor in the blood. When protective doses were given, a definitely larger number of units was found in the blood of the infants that had received viosterol, notwithstanding the fact that the clinical effect was about the same. Evidently the clinical effect does not parallel the antirachitic content of the blood, as tested on rats. Assays of the feces showed that, in general, the absorption of the various antirachitics was relatively the same; when the antirachitic unitage was large, more was recovered from the feces, and when a small number of units was fed, the absolute amount in the feces was small.¹⁵

CONCLUSIONS

A further clinical test was carried out on irradiated milk, "yeast milk," cod liver oil and viosterol, the study being controlled with bio-assays of the various antirachitic preparations. It was found that the antirachitic milks, especially irradiated milk, require a surprisingly small number of rat units (from 35 to 40 daily) to confer protection or effect healing, and that viosterol requires the largest number.

Irradiated milk seems to be the most desirable antirachitic for prevention on a communal scale. Only 20 to 24 ounces daily is needed to assure protection. This therapeutic agent has the advantage of being automatic and inexpensive and of providing calcium and phosphorus as well as the antirachitic factor.

The marked distinction between clinical units and rat units implies that the present method of rating antirachitic agents is misleading. Their respective biologic potencies, as expressed in rat units, are not interchangeable. Each type must be appraised for itself. Its

minimal number of therapeutic units must be ascertained clinically and then expressed in terms of rat units. The wide differences in activity between various antirachitics indicate that a clinical as well as a laboratory pharmacology must be taken into account.

MIKULICZ'S DISEASE AND DIABETES

HENRY J. JOHN, M.D.

CLEVELAND

During the past decade, a number of European investigators have been interested in studying the parotid glands. Many clinical observations have been made, and considerable experimental work has been done in an effort to learn the true function and significance of the salivary glands. In spite of the tremendous amount of work that has been done on this problem, the question as to whether or not the salivary glands have an internal secretion has not yet been answered satisfactorily. Considerable clinical and experimental evidence has accrued to indicate that there probably is an indirect if not a direct relationship between the salivary glands and the glands of internal secretion. That the parotid glands have a function in some way analogous or related to that of the pancreas has been suggested by recent clinical observations and experiments. Swelling of the parotid glands, or Mikulicz's disease, has been observed recently in a number of patients with mild diabetes. Recently I have studied four patients who exhibited this combination of symptoms. So far as I know, this clinical picture has not been described in the American literature, so I am reporting the four cases I have studied together with a brief review of related clinical observations and experiments that have been published in Europe. Most of these articles were reviewed by Charvát¹ last year.

Baccarani and Zagari² in 1903 pointed out that in serious chronic ailments, such as pulmonary tuberculosis and cancer, there are sometimes cirrhotic processes in the salivary glands with atrophy, which leads to cachexia, to serious digestive disturbances, even to death. They initiated substitution therapy with favorable results in such cases by injection of extracts from the parotid glands and also by ligation of the salivary ducts.

There have been innumerable clinical observations which would point to some relationship between the parotid and the endocrine glands. In epidemic parotitis, orchitis in men and oophoritis and mastitis in women are rather common complications. It has repeatedly been stressed that these complications of mumps are much more frequent in patients with well developed sexual function and that they rarely occur in young children or in those past the prime of life. There are also recorded cases of parotitis following gynecologic operations. Mohr² reported that in cases of atrophy of the genital glands there is hypertrophy of the parotids. Haemerli² and also Dalche² reported cases of hypertrophy of the parotid gland in women at the time of the menopause and in men with dimin-

14. In examining infants for rickets, it should be borne in mind that there is not only a rachitic beading but also what may be termed "antirachitic beading." By this is meant an enlargement of the costochondral junctions due to the giving of antirachitic agents for long periods and especially in excessive amounts. Beading of this kind may be mistakenly judged as rachitic in nature and may lead to the inference that the therapy has been ineffective. Associated with "antirachitic beading" one may find hypertrophy of the epiphyses at the wrists, associated with hypercalcification but unaccompanied by any changes in calcium or phosphorus concentration of the blood (Hess, A. F.; Lewis, J. M., and Rivkin, Helen: Clinical Experiences with Irradiated Ergosterol, *J. A. M. A.* 91: 783 [Sept. 15, 1928]). A condition of this kind was emphasized recently by Irish (Irish, H. E.: Skimmed Milk Feeding on Bones of Infants, *Am. J. Dis. Child.* 45: 96 [Jan.] 1933).

2. Cited by Charvát.¹

ished sexual function. In 9 per cent of a series of Polish children, Ehrlich² found enlarged parotid glands which he considered due to endocrine disturbances caused by undernutrition. Apert² described a case in which there was enlargement of the parotid glands in conjunction with a hypofunctioning thyroid gland, and Gourdel² has described the same finding in cases of myxedema. Bauer³ recorded enlargement of the parotid gland in cases of goiter and in men who had testicular tumors. In 1927, Römer⁴ described two cases in which there was enlargement of the parotids with disturbance of thyroid function. Loos² has described the case of a woman, aged 53, who had had noninflammatory swelling of the parotid since she was 8 years old, which he felt was due to some disturbance of the endocrine system.

In 1897, Ferrannini⁵ reported a case of salivary diabetes. The patient had an excessive flow of saliva (several liters in twenty-four hours) which contained dextrose. Glycosuria alternated with and replaced the glycosialorrhea. This case suggested a possible reciprocal relationship between the salivary glands and the pancreas, and Ferrannini's assistant, Farroni,⁶ carried out a series of investigations on the function of the salivary glands.

Farroni⁶ showed that extracts of the salivary glands of cattle exerted a glyco-inhibitory action in rabbits, preventing or controlling glycosuria following the administration of epinephrine, phlorhizin and morphine. In vitro, these extracts exhibited a marked glycolytic action on different sugars. On the basis of these observations, Ferrannini postulated an endocrine action of the salivary glands analogous to that of the pancreas. A decade later, Best, Scott and Banting² found much insulin in the salivary glands, which they thought was due to extravasation from the blood stream. Later Poluffo² studied the pH of saliva in normal persons and in diabetic patients and found that there was no essential difference in the two groups, although, after the administration of insulin, the alkalinity of the saliva increased somewhat.

Saliva causes a diastatic breaking down of the carbohydrates and is necessary for proper gastric digestion. If both parotids are removed from an experimental animal, death from cachexia results within a short time. This was first shown by Baccarani and Morano² in 1902. These experiments were confirmed in 1907 by Hemeter,² who went a step further and showed that, if extracts of saliva were injected or parotid glands implanted into the abdominal wall of parotidectomized animals, marasmus disappeared and the animals lived. Pagliani² also prolonged the life of his experimental animals by injections of saliva, and Goljanitsky⁷ saved his by intra-abdominal implantation of salivary glands.

In 1927, Utimura⁸ found that dogs died within three months after extirpation of the parotid glands, but he did not ascribe death to digestive disturbances as previous workers had done. The dogs displayed marked

weakness and anemia. Utimura⁸ found that after parotidectomy the action of the thyroid was increased, the islands of Langerhans were enlarged, and there was an increase in the amount of liver glycogen. When the submaxillary glands were removed, these changes were reversed, and if both the parotids and the submaxillary glands were extirpated there were no changes in the pancreas and liver.

A year later, Bono Simonetta² excised the parotids, the sublinguals and the infra-orbital glands of rabbits, but his animals lived, and hence he questioned the results of earlier extirpation experiments.

Many investigators have ligated one or both parotid ducts in studying the problem of parotid function. Goljanitsky,⁷ Dobrzaniecki and Michalowski,⁹ Mansfeld and Schmidt¹⁰ and Zimmermann¹¹ have published the results of extensive investigations. Goljanitsky⁷ found that, when one parotid was ligated, changes soon occurred in the other gland. He explained this on the basis of Metchnikoff's theory of cytotoxins. He felt that concomitant disorders of the gonads and parotids could also be explained by the fact that they have related cytotoxins. Mansfeld, proceeding on the assumption that the endocrine organs are glands which have lost their secretory ducts, and that hence any gland of external secretion could be converted into one of internal secretion by depriving it of its excretory duct, anticipated that ligation of the ducts of Steno would convert the parotid glands into endocrine glands with an insulin-like secretion. This hypothesis was based on the embryologic and morphologic similarity of the pancreas and the salivary glands and the fact that both are concerned in the digestion of carbohydrates. When he ligated the parotid glands of dogs, he found that the level of the blood sugar was lowered. Later, the ligated glands were extirpated and the level of dextrose returned to normal. In dogs with experimental diabetes produced by partial extirpation of the pancreas, ligation of the parotid ducts controlled the hyperglycemia. However, ligation of the ducts of Steno had no effect in controlling the diabetes produced by total removal of the pancreas. Mansfeld concluded from these experiments that the parotid glands must produce a substance which stimulates the pancreas to increased function. Seelig¹² and also Dobrzaniecki and Michalowski⁹ repeated Mansfeld's experiments and confirmed his observations.

In 1932, Zimmermann¹¹ made similar studies and also made extensive histologic studies of the parotid glands removed at varying intervals after ligation. These showed a gradual dilatation of the ducts with atrophy and fibrosis of the glandular parenchyma. Goljanitsky⁷ also made comparative histologic studies of the pancreas and the parotid. He felt that the star cells resting on the membrana propria of the secretory canal and the so-called Giannuzzi's moon-shaped cells correspond to the islands of Langerhans in the pancreas. When the parotid duct was ligated, he found that the epithelium disappears and the interstitial tissues hypertrophy, thus stimulating the endocrine activity of the gland. He felt that the internal secretion of the salivary gland has a function similar to

that of insulin and that both hormones are antagonistic to epinephrine.

As the result of these experimental investigations on animals, numerous attempts have been made to treat diabetic patients by ligation of the parotid ducts. After his early experiments, Goljanitsky⁷ reported beneficial results from ligation of the salivary duct in a patient with diabetic gangrene. In 1929, he¹³ described some cases in which ligation of the parotid ducts and transplantation of the submaxillary gland seemed to ameliorate the symptoms of diabetes. Seelig¹² reported favorable results in seven of ten diabetic patients in whom one parotid duct had been ligated. However, in a later publication, dealing with eighteen cases, he¹⁴ concluded that the results of this operation were negligible.

An interesting clinical study was made by Mironescu, Nicolicesco and Stefanescu-Dima.¹⁵ They determined the blood sugar in fifteen patients with epidemic parotitis and found normal values in nine, a slightly increased level in five, and slight hypoglycemia in one. None of these patients had glycosuria.

It is now forty-five years since von Mikulicz¹⁶ described the disease or syndrome that bears his name. The patient he described was a man, aged 42, who had bilateral chronic painless enlargement of the lacrimal glands and of the salivary glands, which could not be accounted for by any of the clinical observations, and hence the symptoms were ascribed to some obscure infection. The patient died later the same year from perityphlitis, and during his last illness the parotid glands decreased rapidly in size and, at the time of death, appeared almost normal. Since von Mikulicz's description, more than a hundred instances have been reported in the literature, but these are not all regarded as authentic cases. Schaffer and Jacobsen¹⁷ have proposed the following classification of cases of enlargement of the parotid gland:

1. von Mikulicz disease:
 - Familial—rare.
 - von Mikulicz disease proper.
2. von Mikulicz syndrome:
 - Leukemia—frequent.
 - Tuberculosis—rare.
 - Syphilis.
 - Lymphosarcoma—frequent.
 - Toxic agents, lead, iodides, etc.
 - Gout.
 - Febris uveoparotidea subchronica.

Last year, Charvát,¹ in addition to a review of the literature on the parotid glands, reported three cases of mild diabetes in which there was also symmetrical painless noninflammatory swelling of the parotid glands, which had persisted from six months to three years. Lymphatic leukemia, syphilis and tuberculosis were ruled out in each case.

Charvát felt that the parotid swelling represented a compensatory hyperplasia of the glandular parenchyma in response to failing insulogenic function or a symptom of endocrine hyperfunction of the salivary

glands, which might account also for the mildness of the diabetic state. In two of these patients, the parotid swelling decreased with treatment for the diabetes.

Flamm¹⁸ became interested in the study of hypertrophy of the parotid glands as a symptom of diabetes mellitus through observing a woman with hypertension who had frequent attacks of swelling of the salivary glands, which were not accompanied by pain, fever or other signs of inflammation. In the intervals between attacks, the parotid glands remained somewhat larger than normal. Later, diabetes mellitus was discovered with continued recurrence of parotid hypertrophy. This caused a peculiar transformation of the features of the face, which Flamm noticed was quite characteristic of a good many patients with diabetes.

In order to approach the study from a different point of view, Flamm decided not to examine the parotid glands of patients with diabetes but to study patients with abnormally large parotid glands. In a group of twenty-seven patients with swelling of the parotid glands, sixteen showed glycosuria and also an increase in the fasting blood sugar. Dextrose tolerance tests showed some decreased sugar tolerance in the other eleven patients. It also was noted that most of these patients belonged to the constitutional type designated as sthenic hypertension diabetes. Flamm¹⁸ offered no direct explanation of the functional processes underlying this hypertrophy of the parotids in diabetic patients, but concluded that it might be interpreted as a compensatory process.

Recently, I have observed four patients with enlargement of the parotid glands and mild diabetes. None of these patients sought medical advice because of the diabetic condition, although in one case diabetes had been diagnosed previously but the patient had not had adequate or systematic treatment. In each instance the enlargement of the parotid glands was noted in the clinical examination, with subsequent detection of glycosuria and hyperglycemia. In none of these cases could the parotid hypertrophy be attributed to any inflammatory or infectious process.

REPORT OF CASES

CASE 1.—A Syrian woman, aged 50, complained chiefly of chronic cough, dyspnea and pain in the chest. The patient was obese, 44 per cent overweight, and her blood pressure was 130 systolic, 80 diastolic. The most significant observations in the physical examination were bilateral symmetrical swelling of the parotid glands, emphysema and increased bronchial sounds in the left side of the chest. A roentgenogram of the chest showed dilatation of the bronchi and fibrosis of the lungs and cardiac hypertrophy. The diagnosis was chronic bronchitis with bronchiectasis and myocarditis. There was marked glycosuria, although the fasting blood sugar was normal. However, a dextrose tolerance test showed decreased tolerance. The diabetes was satisfactorily controlled on a restricted diet. Several infected teeth were removed, and general physical therapeutic measures, including heat and massage, were instituted. The patient's general condition improved somewhat, but her symptoms were not entirely relieved. There was no change in the parotid swelling.

CASE 2.—An Italian woman, aged 37, who appeared about twenty years older, came to the clinic complaining of severe occipital pain. She was very obese, about 55 per cent overweight, and her blood pressure was 139 systolic, 86 diastolic. Aside from the obesity, the only significant physical condition was bilateral enlargement of the parotid glands. A special neurologic examination did not reveal the cause of the severe headaches. A roentgenogram of the skull showed three decal-

cified areas; one, left frontal; one, right temporal, and a rather irregular area well forward at the vertex. The significance of this finding was not determined in relation to the cephalalgia. The cervical sympathetic nerves were injected in an effort to relieve the pain, but this treatment was only partially successful. The laboratory examinations revealed marked glycosuria and hyperglycemia (fasting blood sugar, 214). A diet containing 1,800 calories and 15 units of insulin three times a day were prescribed. The patient has not returned to the clinic since, and nothing is known of the results of treatment.

CASE 3.—An Italian woman, aged 52, complained that for five years she had not been in good health. Her abdomen had been enlarging steadily; there was burning on urination, and during the last year there had been a coarse tremor of the hands and feet, with some numbness and tingling of the feet. The patient had had seventeen pregnancies, with only four children living and well. A number of pregnancies resulted in abortions or stillbirths, and several children died during the first year of life. The patient was short and obese, and her blood pressure was 150 systolic, 82 diastolic. The parotid glands were symmetrically enlarged. The abdominal wall was relaxed and the abdomen markedly distended. A large mass in the hypochondrium was found to be due to ptosis of the liver. Hemorrhoids had been present for twenty-eight years. A typical pill-rolling position of the hands with a coarse intermittent tremor was noted. The fasting blood sugar was 272 mg. per hundred cubic centimeters, and the blood urea 69 mg. The hemoglobin and red blood cell counts were below normal.

The diagnosis was diabetes, Parkinson's disease, pernicious anemia, Mikulicz's disease, obesity and abdominal viscerotoposis. The diabetes was controlled on a diet of 140 Gm. of carbohydrate, 60 Gm. of protein and 111 Gm. of fat, with 10 units of insulin three times daily, but no change was noted in the size of the parotid glands.

CASE 4.—An Italian woman, aged 68, sought relief from intense itching of the skin, which had begun about a week before and had become progressively worse. Nine months before she had had polyuria and had been told by her family physician that she had diabetes. Her diet had been only slightly restricted and she had received no insulin. The polyuria had disappeared. Her blood sugar was 300 mg. per hundred cubic centimeters and she had severe glycosuria. Aside from moderate obesity, bilateral swelling of the parotid glands was the only significant finding in the physical examination. The skin condition was diagnosed as diabetic dermatitis. On a routine diabetic diet of 1,800 calories and 10 units of insulin twice daily, her blood sugar returned to normal, and she was advised to follow this regimen after she left the hospital. At a subsequent examination, the blood sugar had increased slightly, and the insulin dose was increased to 15 units twice a day, which has controlled the diabetes satisfactorily.

COMMENT

All four of these patients were obese, and there was a striking similarity in their facial appearance. Not one of them has been observed more than a few months, and during that time there has been no diminution in the size of the parotid glands. The diabetes was mild in all these cases and was easily controlled with moderate dietary restrictions and small doses of insulin. Whether the parotid swelling represents a compensatory process brought about by decreased pancreatic function, as Charvát and Flamm have suggested, remains an open question. But these cases are reported with the hope that it may stimulate more clinical observations and more interest in the possible relationship between the salivary glands and the pancreas. At present the problem is largely of academic interest, but further experiments and observation may bring forth knowledge that may be of significant importance clinically.

VACCINATION AGAINST WHOOPING COUGH

THORVALD MADSEN, M.D.

COPENHAGEN, DENMARK

As vaccination against whooping cough is still much discussed, the following observations might perhaps be of some interest.

The vaccine used in the State Serum Institute in Copenhagen is always made from several recently cultivated strains of Bordet-Gengou bacilli; forty-eight hour blood agar cultures are emulsified in physiologic solution of sodium chloride containing 1 per cent solution of formaldehyde, so that the suspension contains about 10,000 millions of bacilli per cubic centimeter. The vaccine is given in three injections intramuscularly or subcutaneously with intervals of from three to four days: 0.5, 0.7 and 1.0 cc. This dosage is greater than that usually employed.

As generally maintained, one of the advantages of whooping cough vaccination is the absence usually of severe reactions following the injections, although it would seem correct to call attention to two deaths that have occurred in Denmark. In both cases, the children concerned were new-born in families at the time when whooping cough was present. The physician in charge therefore considered it desirable to vaccinate the new-born children. Immediately after birth one child was given 0.1 cc. of whooping cough vaccine, subcutaneously, causing no symptoms, and four days later 0.15 cc. was given. One-half hour after the last injection, contractions in the arms and legs occurred, followed by cyanosis, hiccup, convulsions and death within a few minutes. The other case, occurring two years later, was that of a child weighing 2,250 Gm., born five weeks prematurely. Eight days after birth, 0.1 cc. of whooping cough vaccine was given, causing no symptoms. Three days later, 0.2 cc. was injected (all injections subcutaneously). Two hours after this injection, the child died suddenly with slight cyanosis but no convulsions or vomiting. At the postmortem examination no definite cause of death could be established. No attempts will be made here to explain these two deaths. In spite of the fact that numerous new-born children have been vaccinated without any reactions, we now do not recommend the vaccination of children under 1 month of age.

Furthermore, some of my colleagues have told me that they have seen considerable malaise following the vaccination.

The reason for the difference of opinion concerning the value of the vaccination lies to some extent probably in the fact that no sufficient distinction has been made between the therapeutic and the prophylactic properties of the vaccine. Most of the reports conclude that if given early in the catarrhal stage the vaccine will have a good effect; the later the vaccine is given in the convulsive stage, the less effect can be expected. This appears from the reports of most of the Danish officers of health and also is the consensus of the Danish pediatric society.¹

The greatest difficulty in the appraisal of the effect of the whooping cough vaccination is that no suitable control material is at hand. Such a control material that

From the State Serum Institute.

is especially well adapted in this respect is found, however, in the Faroe Islands.² The conditions peculiar to these islands cause the whooping cough epidemics to appear in waves separated by quite long intervals entirely free from whooping cough. An epidemic of this kind started in 1923 and continued in 1924. On this occasion, vaccination on a large scale was carried out, 2,094 individuals being vaccinated, whereas this was not possible in 627 cases. The result was that the majority of both vaccinated and nonvaccinated individuals contracted whooping cough. As a prophylactic measure, its value, therefore, was not worth mentioning. On the other hand, only five deaths occurred in the vaccinated group as compared to eighteen deaths in the nonvaccinated group. The mortality in the latter group was therefore twelve times that of the former, and the course of the disease was as a whole much more severe in the nonvaccinated individuals.

Detailed information regarding the disease was obtained by Dr. Zachariassen and is summarized in table 1. The earlier the vaccination was carried out, the better was the effect; the best results were obtained when the vaccination was completed one week before the onset of the disease.

Another whooping cough wave appeared in the Faroe Islands in 1929; Dr. Zachariassen was kind enough to give me his observations. This time, vaccination was carried out in 1,832 individuals, while 446 were not vaccinated. A comparison between these two groups is shown in table 2.

In this epidemic the prophylactic value of the vaccination seems to have been much better than in the first one, 458 of the 1,832 vaccinated avoiding whooping cough, whereas among the 446 nonvaccinated only 8 did not become infected.

The explanation of the favorable results of vaccination in the Faroe Islands probably rests on the following facts: 1. The vaccine was made from young strains.³ 2. The dose used was rather large, a total

A summary of the results of the two epidemics, 1923-1924 and 1929, both of which occurred during the winter, is shown in table 3.

The mortality in the vaccinated group is therefore one sixteenth of that in the nonvaccinated group. This figure is sufficiently large to prove the usefulness of the vaccination when carried out in time. Furthermore, the disease in vaccinated individuals takes a much

milder course and is of shorter duration. It is worth mentioning that no selection whatever was made between the vaccinated, so that the nonvaccinated and vaccinated groups of individuals in both epidemics were quite comparable in respect to age, time of epidemic and surrounding conditions.

LIVER-GASTRIC TISSUE PREPARATIONS IN THE TREATMENT OF PER- NICIOUS ANEMIA

P. J. FOOTS, M.D.

AND

L. G. ZERFAS, M.D.

INDIANAPOLIS

The therapeutic effectiveness of liver and fractions of liver in the treatment of patients with pernicious anemia is well established. Minot, Cohn, Murphy and Lawson,¹ and Zerfas² have demonstrated that the amount of liver extract No. 343 derived from 300 Gm. of whole liver (from 12 to 14 Gm. of the dried powder) is the minimal amount required to produce maximal reticulocyte responses when fed daily by mouth to patients with pernicious anemia in relapse. Sharp,³ Sturgis and Isaacs,⁴ Conner,⁵ Wilkinson⁶ and others have shown that preparations of hog gastric tissue are likewise effective when fed daily in amounts equivalent to from 200 to 300 Gm. of fresh stomach tissue (from 30 to 40 Gm. of desiccated material). Following the work of Castle and his associates,⁷

The Effect of the Administration to Patients with Pernicious Anemia of the Contents of the Normal Human Stomach Recovered After Ingestion of Beef Muscle, Am. J. M. Sc. 178: 748 (Dec.) 1929. Castle, W. B., and Townsend, W. C.: Observations on the Etiological Relationship of Achylia Gastrica to Pernicious Anemia: II. The Effect of the Administration to Patients with Pernicious Anemia of Beef Muscle After Incubation with Normal Human Gastric Juice, ibid. 178: 764 (Dec.) 1929. Castle, W. B.; Townsend, W. C., and Heath, C. W.: Observations on the Etiological Relationship of Achylia Gastrica to Pernicious Anemia: III. The Nature of the Reactions Between Normal Human Gastric Juice and Beef Muscle Leading to Clinical Improvement and Increased Blood Formation Similar to the Effect of Liver Feeding, ibid. 180: 305 (Sept.) 1930.

Reimann⁸ reported a marked increase in the potency of liver when it was digested in normal human gastric juice. Walden and Clowes⁹ obtained a very active preparation made by the interaction of liver or liver extract No. 343 with small amounts of fresh hog gastric tissue, indicating that from 4 to 6 Gm. was as effective therapeutically as from 12 to 17 Gm. of liver extract No. 343 or from 30 to 40 Gm. of desiccated whole stomach.

We¹⁰ have since demonstrated that when subminimal amounts of liver extract No. 343 (that derived from 100 Gm. of liver) were incubated with 100 cc. of normal human gastric juice—itself inactive—for four hours at 40 C. and fed daily to patients with pernicious anemia, maximal reticulocyte responses were obtained. The explanation for the enhanced activity of subminimal amounts of liver and fractions of liver, when incubated with small amounts of fresh hog gastric tissue or with normal human gastric juice, remains to be determined. Further experiments are in progress which may help to explain the enhanced potency of such preparations.

ment were too high for reticulocyte responses to be obtained, have been followed as outpatients, at monthly intervals, for from four and one-half to thirteen months.

RETICULOCYTE RESPONSES

In table 1, the height of the reticulocyte responses, the initial red blood cell counts, the percentages of hemoglobin and the level of the blood at the end of the first month of treatment may be found. Except in a few instances, the absolute number of reticulocytes obtained compares favorably with that obtained by Minot and his associates and by one of us (L. G. Z.).

Case 3 did not show a maximal response of the reticulocytes when nine capsules of Extralin were given daily. Subsequently, an increase of reticulocytes up to 9 per cent (absolute number 168,300) was obtained when the amount of liver extract No. 343 derived from 300 Gm. of whole liver was administered daily. The red blood cell count and hemoglobin did not respond, however, until liver extract was given by injection. Patients 4, 8 and 9 had had slight reticulocyte responses immediately preceding the Extralin therapy, so that

* These patients had had slight reticulocyte responses to other medication just previous to beginning Extralin therapy.

Our purpose in this paper is to report the clinical results observed when the material¹¹ prepared by Walden and Clowes was fed daily to patients with pernicious anemia. Many of the lots were experimental in character and contained varying amounts of liver or fractions of liver and hog gastric tissue. In the preparations used, the proportion of original fresh liver, or extract No. 343 derived therefrom, to that of fresh hog gastric tissue varied from 20 to 2 parts of liver to 1 part of stomach. The weight of the material contained in twelve capsules varied between 5 and 6 Gm., averaging 5.8 Gm.

To test the potency of this material in the treatment of patients with pernicious anemia, two methods were employed: 1. In a small series of patients who were in relapse at the beginning of therapy, the reticulocyte response and subsequent increase in red blood cells and hemoglobin following the administration of this material was observed. 2. A larger group of patients, most of whose red blood cell counts at the beginning of treat-

maximal responses could not be expected. Accompanying the reticulocyte responses there was the usual marked clinical improvement of the patients.

In table 2 are recorded the reticulocyte responses of four patients who have responded both to the amount of liver extract No. 343 derived from 300 Gm. of liver and to Extralin. It is evident from this table that twelve capsules of Extralin produced as great, if not greater responses of the reticulocytes than did the amount of liver extract No. 343 derived from 300 Gm. of whole liver, when tested on the same patients. Nine capsules daily seemed to be definitely submaximal.

The red blood cell counts of eleven patients who had had reticulocyte responses and who had received only Extralin therapy averaged 3.67 million at the end of the first month of treatment, as compared with 3.5 million reported by Zerfas when the amount of liver extract No. 343 derived from 300 to 600 Gm. of liver was fed daily, and 3.72 million reported by Minot when the amount of liver extract No. 343 derived from 600 Gm. of liver was administered. Six patients who received twelve capsules a day until their red blood cell counts reached normal levels required on the average 3.1 months, while one patient who received nine capsules a day required seven months, thus indicating the inadequacy of this daily amount of material. Minot and his associates stated that "after two months of adequate therapy with liver, red blood cell count

11. The substance made by the interaction of liver or fractions of liver with hog gastric tissue has been designated by Walden and Clowes as "Extralin." The preparations employed have been supplied by Eli Lilly & Co.

vicinity of 5 million per cubic millimeter are to be expected." A group of eleven of our patients, selected at random, treated with adequate amounts of liver extract No. 343, required on the average 2.6 months for the red blood counts to reach normal levels.

MAINTENANCE DOSAGE

Table 3 shows the average red blood cell counts, the percentages of hemoglobin, and the length of time the various patients have remained on Extralin therapy, as well as similar figures for some of the patients who received other medication.

Sixteen patients have received nine capsules a day over periods of time varying between five and one-half and thirteen months (average 9.6 months). Of these, four have been unable to maintain their red blood cell counts at normal (4.5 million per cubic millimeter), while eight have been unable to maintain the hemoglobin at or above 85 per cent. It was observed that one patient who received from three to six capsules a day did not maintain the red blood cells and hemoglobin percentage at normal levels but subsequently has been able to do so for a period of six months while taking nine capsules a day. Twelve of the sixteen patients receiving

above five million while taking twelve capsules of Extralin daily. The percentage of hemoglobin, however, still remains subnormal. Thus, with the three types of therapy employed, the hemoglobin percentage has not increased satisfactorily, though the level of the red blood cells can be maintained at normal. The use of large daily amounts of iron is definitely indicated in this instance. Patient 36, likewise, failed to maintain a normal red blood cell count while receiving weekly injections of liver extract; yet satisfactory progress has been made during the past nine months when twelve capsules of Extralin a day have been administered.

Six of the eight patients who received nine capsules of Extralin a day and who were unable to maintain the percentage of hemoglobin at normal levels had some complication, such as moderate to advanced central nervous system involvement, generalized arteriosclerosis, chronic infections, or other noninfectious complications, though a similar proportion of the patients who have maintained the hemoglobin at normal levels have also had complications. Of the seventeen patients receiving twelve capsules a day who were unable to keep the percentage of hemoglobin above 85, thirteen

nine capsules of Extralin a day had been observed by this department for a period of one year or more, preceding the commencement of Extralin therapy; of these, eight failed to maintain normal red blood cell counts when taking daily the amount of liver extract No. 343 derived from 100 to 400 Gm. of whole liver, although all but one of these eight patients have done so while taking nine capsules of Extralin a day.

The thirty-one patients who received twelve capsules a day for from four and one-half to thirteen months (average 8.3 months) maintained normal red blood cell counts, although seventeen patients of this group were unable to maintain the hemoglobin at or above 85 per cent. Fourteen of the thirty-one patients had been treated with other therapeutic substances for at least eight months preceding the use of Extralin, and only five had failed to maintain their red blood counts at normal levels while taking the amount of liver extract derived from 200 to 400 Gm. of liver daily.

Patient 37 was unable to maintain a normal red blood cell count and percentage of hemoglobin when the amount of liver extract No. 343 derived from 300 Gm. of whole liver was given daily during a period of twelve months. Following this, the amount of liver extract No. 343 derived from 100 Gm. of liver was injected intravenously at weekly intervals for a period of thirteen months, and, while the red blood cell count did reach a slightly higher level, the percentage of hemoglobin decreased. For a period of six months now, this patient has maintained a red blood cell count of

had complications, while only seven of the remaining fourteen had complications. Three of the four patients who were unable to maintain the red blood cell counts at normal while taking nine capsules a day also had some type of complication.

The three patients who died during treatment had one or more complications in addition to marked central nervous system involvement. Patient 12, aged 66, owing to voluntary omission of therapy for about two weeks before death, had a systemic relapse with exacerbation of chronic cystitis and died following the development of bronchopneumonia. Patient 25, aged 60, received twenty-four capsules of Extralin a day during the last four months of her illness but died following an acute exacerbation of a pyonephrosis. Patient 28, aged 57, had mild diabetes mellitus and markedly deforming hypertrophic arthritis of six years' duration and died following an acute cardiac failure, although the patient had been taking regularly twelve capsules of Extralin a day.

All the patients who have received both types of medication prefer to take the capsules rather than the powder.

COMMENT

The results obtained indicate that the product of the interaction of a subminimal amount of liver or liver extract and a small amount of hog stomach tissue, as described by Walden and Clowes, is highly effective in the treatment of pernicious anemia. The maximal reticuloocyte responses obtained demonstrate that twelve

capsules are equivalent to the amount of liver extract No. 343 derived from 300 to 400 Gm. of whole liver. However, it appears that the time required for the patient to reach a normal red blood cell level is slightly longer when Extralin is used. Although essentially all the patients received both types of therapy gratis, we feel that many of them have taken the capsules containing Extralin with greater regularity than they did the liver extract and have therefore maintained their red blood cell counts at much higher levels. The fact that the patients prefer the capsules must be considered in comparing the ability of the two preparations to

The fact that 50 per cent of the patients continue to have subnormal hemoglobin values, although their red blood cell counts have been maintained at normal levels, indicates that iron in large doses should be used in conjunction with the Extralin. Seven of the patients are now receiving iron and ammonium citrate in doses of 45 grains (3 Gm.) a day. Except for one patient, all have shown an increase in the percentage of hemoglobin during the first month on this additional therapy. These patients have not received the iron for a sufficient length of time to determine whether the hemoglobin will return to normal and be maintained at that

* Patients in partial relapse, indicating that the maintenance dose employed was inadequate.

† Patients died during therapy with red blood cell counts at or near normal levels.

‡ Patients given liver extract No. 343 derived from 100 Gm. of liver parenterally per week.

maintain the red blood cell counts at normal levels. Many of the patients have not been studied for a sufficient length of time as yet regarding their maintenance dosage requirements, but the fact that twenty-five patients have maintained normal red blood cell counts for at least ten months, while taking from nine to twelve capsules a day, indicates that this amount of material furnishes sufficient "active principle" for the treatment of a goodly percentage of persons with pernicious anemia. The data also indicate that the contents of twelve capsules of Extralin administered daily is preferable as a maintenance dose in the majority of patients. As with any type of therapy for pernicious anemia, continued observation of the patients is necessary in order to determine whether the individual is receiving a sufficient amount of the active principle.

level. Minot and Castle,¹² Beebe and Lewis,¹³ Fouts and Zerfas¹⁴ and others have indicated that in some cases of pernicious anemia the addition of iron to the therapy is highly advantageous.

CONCLUSIONS

1. The product of the interaction of subminimal amounts of liver or liver extract and small amounts of hog gastric tissue (Extralin), as described by Walden and Clowes, is highly effective in the treatment of patients with pernicious anemia.

13. Beebe, R. T., and Lewis, G. E.: The Maintenance Dose of Potent Material in Pernicious Anemia, *Am. J. M. Sc.* 181:796 (June) 1931.

14. Fouts, P. J., and Zerfas, L. G.: Maintenance Dosage of Liver Extract in the Treatment of Pernicious Anemia, *Ann. Int. Med.* 6:1298 (April) 1933.

2. Twelve capsules of Extralin daily produced a maximal response of the blood and was adequate to maintain the blood at normal levels in the majority of patients.

3. The additional use of iron in large daily amounts is indicated in patients with subnormal hemoglobin values.

Locke and Tenth streets.

ACTIVE IMMUNIZATION AGAINST DIPHTHERIA

A RAPID METHOD WITH A SINGLE INJECTION

HENRY W. STRAUS, M.D.

BROOKLYN

The importance of active immunization against diphtheria in the control of this disease has been amply demonstrated. This fact is well illustrated in a recent report on this question published in the weekly health bulletin of the Connecticut State Department of Health. In 1920, previous to the introduction of active immunization, the incidence of diphtheria for each 100,000 inhabitants of that state was 269.4. In the succeeding years, with a single exception, this rate gradually declined until in 1932 it reached the low point of 15.8. It is estimated that, during this period, 31,511 persons in Connecticut had escaped the disease as a result of the preventive measures which had been taken.

Two preparations have previously been employed: (1) slightly toxic mixtures of toxin and antitoxin; and (2) detoxified toxin or toxoid. The latter has practically displaced toxin-antitoxin mixtures, especially in the immunization of young children. Its advantages over the older preparation are that (a) toxoid contains no foreign serum, (b) it is stable, (c) it is nontoxic and (d) it is superior as an antigen.

The technic recommended by the New York City Department of Health originally required three injections of 0.5 cc. each, to be given at weekly intervals. More recently, two injections of 1 cc. each, given two weeks apart, have been recommended. The toxoid contains from 5 to 10 antigenic units per cubic centimeter. The practical advantages in reducing the number of injections while maintaining a high rate of immunization are obvious.

With the toxoid preparation to be described, it has been possible to immunize actively over 99 per cent of the cases in the series with but a single injection. The principle involved is that of continuous antibody stimulation afforded by the slow absorption of small amounts of concentrated antigen.

It has been stated by Glenn¹ that the immunity produced by the injection of an antigen in a nonimmune animal does not depend entirely on the total amount of antigen injected. The time spacing of the stimulus or the continuance of the stimulus is of great importance. If the antigen is rapidly absorbed and eliminated, only slight stimulation may occur even when large doses are injected.

PREPARATION²

The material used in this study was prepared in the following manner: Diphtheria toxoid (M. L. D. 500

per cubic centimeter; $L + 0.13$; $L. F. 0.1$), 7,300 cc., was placed in cellophane bags and fanned at room temperature until the volume was reduced to 250 cc. The dark colored granular precipitate that formed was removed by centrifugation. The supernatant fluid was diluted up to 730 cc. in the process of twenty-four hour dialysis in a cellophane sac and by the addition of distilled water. Phenol (0.5 per cent) was added and the solution was filtered through a Berkefeld candle. The least fatal dose of the concentrated solution was $0.014 \pm$.

In a similar way, the solution was further concentrated to 73 cc. (100:1 concentration). This was preserved, after Berkefeld filtration, with merthiolate in a final concentration of 1:10,000. This concentrated fluid was found to contain 300 flocculating units per cubic centimeter.

Two batches of the lanolin mixture were prepared as follows: Batch 301-H-11 was made by thoroughly mixing, at 42 C., 100 cc. of sterile hydrous wool fat and 50 cc. of concentrated diphtheria toxoid. One cc. of this mixture thus contained 100 flocculating units and 0.2 cc. contained 20 flocculating units. Batch 301-H-12 was made in the same way as 301-H-11 with the exception that, to each quantity of 0.2 cc. of the mixture, 0.05 cc. of sterile olive oil was added.

The material was received in individual miniature antitoxin syringes, each containing a single dose. The preparation is of the consistency of a soft wax and is easily expelled from the syringe.

ADMINISTRATION AND RESULTS

The air is first expelled from the syringe. Then, under aseptic precautions, the contents amounting to 0.2 cc. or 0.25 cc. are injected deeply into the deltoid muscle with the needle at a right angle to the skin. The intramuscular route is chosen for the same reasons that it is preferred as the site of injection for drugs suspended in oils. If the injection is not delivered intramuscularly, a tiny mass may be felt at the injected site until complete absorption takes place.

The toxoid-lanolin mixture was injected in 103 subjects, all but five of whom were children. The five adults were nurses in training. The ages of the children varied from seven and a half months to twelve years. The largest number were of preschool age. They were selected from the pediatric outpatient department of the Brooklyn Jewish Hospital and so were representative of the poorer class of the city's population. In each case, a Schick test was done on one forearm and a control with heated toxin on the other forearm. The test material used was that regularly supplied by the city department of health and was well within the expiration date printed on the package. Schick and control tests were read on the third to the fifth day. Those showing a positive Schick and negative control were given the immunizing injection.

As it was desired to learn how soon after injection active immunity could be demonstrated, various members of the group were given Schick tests at intervals varying from three to eight weeks. Although the numbers in each group are too small for the percentages to have a statistical value, it is nevertheless interesting to note that active immunity as evidenced by the reversal of the Schick test from positive to negative

was demonstrated in a large percentage of the cases in from three to four weeks after the single immunizing injection. In one of the adults, the Schick test was negative two weeks after the immunizing injection. Table 1 shows the development of immunity by weeks. Table 2 is a summary of the entire series.

TABLE 2.—*Summary of Results Obtained in One Hundred and Three Patients*

| Number Receiving Single Intramuscular Injection of Mixture of Toxin and Hydrous Wool Fat | Schick Negative Within Two Months | Per Cent |
|--|-----------------------------------|----------|
| 103 | 102 | 99 |

Those who still had a positive Schick test two, three or four weeks after injection (fifteen out of eighty-two) were given a Schick test a second time two weeks later and, with a single exception, were then found negative. In the group in which Schick tests were made from five to eight weeks after the immunizing injection, only one out of thirty-six was Schick positive. This one remained positive four months after injection. With the exception of the last case, none were given additional Schick tests more than twice and none were given more than the one immunizing dose. For practical purposes and to obviate the necessity for additional Schick tests, it seems proper that the Schick test be repeated two months after the immunizing injection. Of the 103 cases in this study, 102, or 99 per cent, were Schick negative within two months.

REACTIONS

No reactions were observed in children under five years of age. In the school age group there was an occasional complaint of soreness in the arm for a day or two with slight local redness and, in one case, a temperature of 101 during the first twenty-four hours. In the adult group, five who had positive Schick but negative control reactions were included in the series. They complained only of a heavy feeling in the arm. Five other adults (not included in the series) who gave positive Schick and control tests were given the injection. Of these, two gave severe reactions with a rise of temperature to 102, headache, malaise, a large area of local redness with induration, and regional adenitis. The fever subsided in twenty-four hours. The three remaining persons had mild local reactions without constitutional symptoms. The reactions to be expected, then, are the same as those obtained with ordinary toxoid. They are infrequent and quite mild in older children and absent in those of preschool age. The more severe reactions are to be expected in those patients who give positive reactions to both Schick and heated control material.

SUMMARY AND COMMENT

A concentrated diphtheria toxoid incorporated in hydrous wool fat has been used for active immuniza-

tion. Immunity was established in 99 per cent of 103 cases within two months following a single injection. It is believed that the slow absorption and elimination afforded by the hydrous wool fat is mainly responsible for the good results obtained. This effect may be obtained in other ways, as for example with alum treated toxoid, as reported by Park and Schroder,³ who gave three injections of 0.5 cc. each at weekly intervals. Wells, Graham and Havens⁴ were able to induce immunity in 94 per cent of ninety-eight children after eight weeks with a single injection of 1 cc. of the alum treated toxoid. There seems to be no doubt that effective active immunization against diphtheria through a single injection is an accomplished fact.

CONCLUSIONS

A concentrated diphtheria toxoid incorporated in hydrous wool fat has been injected intramuscularly and actively immunized 99 per cent of 103 patients within a period of two months. In the majority of cases, immunity developed in from three to four weeks and, in one case, as early as two weeks.

Because of the early development of active immunity, a preparation such as that described may have a practical usefulness in checking an epidemic of the disease. A single injection method has obvious practical advantages.

ACTIONS AND USES OF DINITRO-PHENOL

PROMISING METABOLIC APPLICATIONS

W. C. CUTTING, M.D.

H. G. MEHRTENS, M.D.

AND

M. L. TAINTER, M.D.

SAN FRANCISCO

We have recently shown in a series of papers¹ that alpha-dinitrophenol markedly augments metabolism in doses which are not demonstrably harmful. As this drug may have a number of important clinical applications, it seems desirable to present a summary report of its pharmacologic and therapeutic effects, and to point out certain potential dangers in, and limitations to, its use.

During the World War, dinitrophenol was called to the attention of French physicians by cases of poisoning from it in munitions factories. Only incomplete investigations of the actions of the compound were made at that time, as judged by published reports. Recently, Magne, Mayer, Plantefol and others² have extended or completed work begun some years previously but reported simultaneously with our entirely independent studies. We are in general agreement with them as to the main pharmacologic actions of the drug. The

experimental studies have been extended by us and certain possible clinical uses established; summaries of these are given in this report.

GENERAL PROPERTIES

Alpha-dinitrophenol (1-2-4) ($C_6H_3(NO_2)_2OH$) is a yellow crystalline solid, slightly soluble in water, more soluble in alcohol or ether. Solutions may be made up to 3 per cent in water by heating with the addition of

Chart 1.—Effect of a single oral dose of dinitrophenol on the basal metabolic rate.

half the weight of sodium bicarbonate. The melting point is 114 C. It is a dye which is closely related chemically to trinitrophenol (picric acid) and is used as an indicator for hydrogen ion concentrations in the Michaelis technic.³ The dye is readily obtainable on the market in pure form and is rather cheap, which at once indicates a point of superiority over other metabolic stimulants in general use. We have administered it to patients in gelatin capsules, preferably after meals, to avoid irritation of the stomach. To animals, it may be administered in solution by injection, or gastrically.

PHARMACOLOGIC ACTIONS

When dinitrophenol is given to experimental animals, it causes an increase in metabolism within one minute after injection, or somewhat more slowly when given gastrically. The increase in metabolism with doses of 10 mg. per kilogram or less is about 50 per cent. With higher doses, metabolism may be increased fourfold or more, until the animal produces heat so fast that it may be killed by the resulting fever. Return of the metabolism to normal levels may require from six to forty-eight hours, depending on the dose and the route of administration. The increase in metabolism is due to a direct stimulation of cellular metabolism and is not accompanied by an increase in muscular activity. This tremendous upswing of metabolism is not accompanied by important changes in the circulatory system unless asphyxia results from inadequate oxygenation of the blood. Then there may be acceleration of the pulse and rise of blood pressure. There is, however, a very marked increase in respiration, which may be a response to the increased oxygen need or to carbon dioxide production. The respiratory quotient decreases, indicating that the food used for energy is not entirely carbohydrate but must also include fat or protein. The thyroid and suprarenal glands are not indispensable to the metabolic response, since their removal does not interfere with the drug's actions. However, in diabetic

dogs,⁴ dinitrophenol has a greatly increased toxicity, for which there is as yet no adequate explanation. Repeated administrations of the drug for from two to three months to dogs in doses just short of fatal have not resulted in significant injury to important organs, as shown by studies of the urine, icteric index, van den Bergh test, and organs at autopsy and tissues microscopically. The details of these and other pharmacologic and physiologic studies are being published in special journals.

CLINICAL ACTIONS

The actions of dinitrophenol in man agree closely with those in animals when equivalent doses are used.

In eight patients, single doses of from 3 to 5 mg. per kilogram of body weight were given orally to determine the effect on the basal metabolic rate. This was increased from 20 to 30 per cent in the first hour and was maintained at this level for about twenty-four hours. Then it gradually began to fall, reaching normal on the third day. Chart 1 shows a typical result after a dose of 3.5 mg. None of the subjects experienced or showed signs of nervousness, anxiety, trembling, hunger or palpitation. Given orally or subcutaneously, these doses caused no changes in temperature, respiration or pulse rate even after two months of daily administration. Single doses between 5 and 10 mg. per kilogram caused no changes in temperature, pulse or respiration but did make the subjects sweat copiously. Three administrations of single doses of more than 10 mg. per kilogram gave increases in temperature of 3 degrees C. or more, in respiration of 15 to 30 per minute, and of pulse 20 to 30 per minute, all commensurate with the pyrexia. The latter doses are considered too dangerous for routine use.

Daily oral doses of from 3 to 5 mg. per kilogram were given to nine patients for periods of from one to ten weeks. In six of these patients the metabolism was determined repeatedly and found to be maintained at an average of 40 per cent above the initial level. When the drug was discontinued, the rate fell to normal by

Chart 2.—Effects of repeated daily oral doses of dinitrophenol on basal metabolic rate and body weight, and return of metabolism to normal after administration has been stopped.

the third or fourth day. The metabolic rate and weight changes in one such patient are shown in chart 2.

All these subjects lost body weight without resort to dietary restrictions. The maximum total loss in any patient was 9 Kg. (20 pounds) in ten weeks. The greatest rate of loss was 1.7 Kg. ($3\frac{7}{10}$ pounds) a week after a daily dose of 3 mg. per kilogram. The average loss for the entire group was 0.9 Kg. (2 pounds) a week. More vigorous dosing, perhaps combined with

4. Tainter, M. L.; Boyes, J. H., and De Eds, F.: *Arch. internat. de pharmacodyn. et de therap.*, to be published.

dietary control, would probably cause more rapid loss of weight. However, we have not felt justified, from our knowledge of the drug's actions, to induce loss of weight more rapidly. These patients did not suffer from any deleterious symptoms as a result of their reducing treatment. On the contrary, they felt better and more active than before.

COMMENT

Preliminary results indicate that dinitrophenol can satisfactorily increase metabolism for therapeutic purposes in patients. The limiting factor would seem to be the fever caused by the increased heat production. The metabolism has been maintained at a rate 50 per cent above normal for months, with no deleterious symptoms, such as the hyperirritability caused by equivalent doses of thyroid gland. Therefore, dinitrophenol offers this advantage over thyroid. It would appear generally useful for increasing the metabolic rate, experimentally and therapeutically.

Oral administration of the drug to obese patients in daily doses of about 3 mg. per kilogram has resulted in steady reduction of their weight, without demonstrable side-actions. Accordingly, extended trials in this clinical condition are justified. The pharmacologic evidence indicates a usefulness of the drug in hypothyroidism and other states of depressed metabolism.

In view of extended clinical applications which the drug may receive, it is desirable to indicate possible dangers from and limitations to its use. First, continuous administrations in animals and patients have been made for periods not longer than three months, and none have been made in patients with serious disease. Therefore, we cannot be sure that manifestations of toxicity may not appear after more prolonged administration, or in important disease states. Secondly, an increased toxicity of the drug is manifested in the experimental diabetes of dogs, although this may not hold in clinical diabetes. The drug would be of great value in this disease if it would enable the diabetic individual to burn carbohydrates, since it is a powder, readily taken by mouth, with an effect persisting several days after a single oral dose. Any attempt to evaluate its usefulness in clinical diabetes should be undertaken with great caution. Thirdly, excessive doses of dinitrophenol may cause a fatal hyperpyrexia. Finally, the possibility of an idiosyncrasy such as an unusual sensitivity or atypical response to the drug should be kept in mind, although we have not seen unusual reactions. In view of these things, we urge that, for the present, dinitrophenol be used only as an experimental therapeutic procedure in carefully selected patients under close observation by the physician.

CONCLUSIONS

1. Dinitrophenol possesses prompt and striking pharmacologic actions, which are similar in animals and men.
2. The outstanding actions are sustained increases in metabolism and body temperature, enormous activity of all metabolic functions, and fatal pyrexia with excessive doses.
3. Doses within therapeutic range cause in man significant increases in metabolism without fever, which may be useful in treatment of obesity, hypothyroidism, and similar depressed metabolic states.
4. There are limitations to and possible dangers from the use of the drug clinically. It should be used only under strictly controlled conditions.

ACUTE EPIDEMIC POLIOMYELITIS
COMPLICATING PREGNANCY

M. BERNARD BRAHDY, M.D.

MOUNT VERNON, N. Y.

AND

MAURICE LENARSKY, M.D.

Associate Attending Physician and Resident Physician, Respectively,
Willard Parker Hospital, New York

NEW YORK

The occurrence of epidemic poliomyelitis during pregnancy raises several questions. How often does it occur? Should the patient go to term and, if she does, what will be the effect on the labor? Will a viable infant be born? If so, what are the probabilities of intra-uterine infection?

There is no unanimity of opinion as to the frequency of poliomyelitis occurring during pregnancy, nor as to the susceptibility of gravid women to the disease. Aycock¹ believes that poliomyelitis occurs more frequently in the latter part of pregnancy than would normally be expected if the condition had not predisposed to the disease. Jungeblut and Engle² state that early pregnancy and early infancy are the high-water marks of natural resistance to poliomyelitis. The same authors examined the blood of ten women at various stages of pregnancy and found an apparently higher individual virucidal titer than is commonly found in normal persons. Aycock and Kramer³ found no greater percentage of immunity among pregnant women than among the urban adults in general. Alpers and Palmer⁴ and McGoogan⁵ state that poliomyelitis complicating pregnancy is rare.

McGoogan found five cases reported in the literature during the last twenty-five years and adds three of his own, observed in Nebraska over a period of five years. This gives, we believe, the false impression that poliomyelitis complicating pregnancy is extremely rare. Probably many cases observed are not reported. During 1931, three pregnant women with poliomyelitis were admitted to the Willard Parker Hospital (table 1). The total number of patients with poliomyelitis admitted during that year was 1,010. There were thirty over 19 years of age; of these, fifteen were women.

REPORT OF CASES

A summary of the three cases follows:

CASE 1.—D. S., a white primipara, aged 22, was admitted to the Willard Parker Hospital during the ninth month of her pregnancy with a paralytic poliomyelitis of seven days' duration. Her past history was essentially negative. She had uncomplicated measles at 15 years, diphtheria at 17 years and pertussis at 18 years. Her pregnancy up to the present illness had been uneventful. Nine days before admission she had headache, backache, fever and vomiting. Two days later there was weakness of the legs, which progressed to complete paralysis of the right lower extremity and almost complete paralysis of the left lower extremity. The spinal fluid, examined four days before admission was reported as positive for poliomyelitis.

The patient was well developed and well nourished. She complained of backache and pains in the legs and had a little

5. McGoogan, L. S.: Acute Anterior Poliomyelitis Complicating Pregnancy, Am. J. Obst. & Gynec. 24: 215 (Aug.) 1932.

difficulty in sitting up. There was complete flaccid paralysis of both lower extremities, except for the power to move the toes of the left foot. All deep reflexes of the lower extremities were absent. The superficial abdominal reflexes were present but diminished. Otherwise the neurologic examination was negative. The temperature was 99 F. and the pulse 100. The fundus of the uterus was felt just under the xiphoid process. The fetus was in the left occipito-anterior position, the head not engaged. The fetal heart sounds were of good quality and 120 per minute. The patient expected to deliver in two weeks.

The temperature remained normal. The blood pressure was normal and the blood Wassermann reaction was negative. There was no change in the paralysis during the patient's stay in the hospital. After nine days she was discharged to complete her isolation period at home.

Eleven days after discharge, the patient went into labor and was delivered at the Flushing Hospital. Her obstetrician, Dr. J. C. Cohn, wrote us as follows: "The labor was similar to that of the average primipara. After sixteen hours the head was at the perineum and she was delivered by low forceps to save her the strain of the second stage. Her puerperium was normal and uneventful. The baby was normal, weighed 8 pounds and 14 ounces (4,025 Gm.) and is perfectly well now (at 1 year of age)." Five months after discharge the mother was able to get around unaided and a year later walked with only a slight limp of the right leg.

was 140 systolic, 90 diastolic. Delivery was expected early in April, but on February 21 the patient was admitted to the hospital because of labor pains. The same day the patient delivered a normal female infant weighing 4 pounds and 14 ounces (2,210 Gm.). Delivery was spontaneous after a labor of twenty-five hours. There was no excess bleeding, no instrumentation and no laceration. The infant was discharged well at sixteen days of age with a diagnosis of prematurity. There was no paralysis. The mother was examined at various intervals for six weeks postpartum. Her puerperium was normal and uneventful. She walked with a limp of the right leg. A year later (March, 1933), the family was visited by one of our social workers. She found the mother in good health with a barely noticeable limp of the right leg. Her baby is a well developed and well nourished normal infant.

CASE 3.—D. M., a white primipara, aged 19, was admitted to the Willard Parker Hospital during the second month of her pregnancy with a paralytic poliomyelitis of eight days' duration. Her past history was essentially negative. The beginning of her last menstrual period was nine weeks before admission. Morning nausea had been present for one month.

The present illness began nine days before admission with headache, backache, fever, vomiting and pains in the back of the neck and in the legs. The following day she was unable to walk. The day before admission the spinal fluid was found under increased pressure and contained 50 cells per cubic milli-

TABLE 1.—Cases at Willard Parker Hospital in 1931

| Case | Age, Years | Number of Pregnancy | Duration of Pregnancy | Paralysis | Delivery | Child | Follow Up: After 1 Year |
|------------|------------|---------------------|-----------------------|---|--|------------------|--|
| D. S. | 23 | First | 9 mos. | Both lower extremities | Normal, term | Normal | Mother: Slight limp of right leg Baby: Normal, well developed and well nourished |
| F. S. | 23 | First | 4 mos. | Right lower extremity | Premature, normal | Normal premature | Mother: Barely noticeable limp of right leg Baby: Normal, well developed and well nourished |
| D. M. | 19 | First | 1½ mos. | Both lower extremities complete; back and abdomen partial | Abortion at 2 mos. Abortion during 3d month of second pregnancy | | |

CASE 2.—F. S., a white primipara, aged 23, was admitted to the Willard Parker Hospital, Oct. 5, 1931, during the fourth month of her pregnancy, with a paralytic poliomyelitis of eight days' duration. Her last menstrual period was June 28, 1931. Her past history was essentially negative. Twelve days before admission she had headache, fever, vomiting and pains in her legs. Four days later there was weakness of both lower extremities.

The patient was well nourished and well developed and did not appear acutely ill. She complained of backache and pains in the legs. There was stiffness of the neck and lower part of the spine. There was marked weakness of all the muscle groups of the right lower extremity. The knee jerk on the right was absent, but the achilles reflex was present. The deep reflexes of the left lower extremity were sluggish. Otherwise, the neurologic examination was negative. The fundus of the uterus was midway between the symphysis pubis and the umbilicus. The temperature was 99 F. and the pulse 100. The spinal fluid was under slightly increased pressure; there were 20 mononuclear cells per cubic millimeter, and the albumin, globulin and sugar content were normal.

During her stay in the hospital she complained at times of backache and pains in the lower extremities. There was some difficulty in voiding during the first few days, but catheterization was not necessary. Constipation was troublesome. There was no apparent change in the paralysis. Her quarantine period was over after ten days in the hospital and she was discharged, as she requested.

She attended the outpatient department of the Misericordia Hospital. Jan. 22, 1932, she had swollen ankles and puffy eyelids, saw spots before her eyes and had a blood pressure of 150 systolic, 114 diastolic. For the next two weeks she was confined to bed. She had vomiting spells for a few days. On February 5, there were no complaints and the blood pressure

meter, 95 per cent of which were mononuclears, a slightly increased amount of albumin and globulin and a normal amount of sugar.

The patient was well developed and well nourished and did not appear acutely ill. She complained of pains in her back, legs and abdomen. The temperature was 99.6 F. and the pulse 80. There was stiffness of the neck and back. There was a complete flaccid paralysis of both lower extremities. All deep reflexes were absent. There was considerable weakness of the abdominal and back muscles. The abdominal reflexes were absent. The patient could not sit up unaided.

During the first few days in the hospital there was some difficulty in voiding, but catheterization was not necessary. Constipation was troublesome. The pains in the back and legs gradually subsided. During her stay in the hospital there was no change in the paralysis. Thirteen days after admission the patient was discharged to an orthopedic hospital.

The following data were obtained from the case record at the orthopedic hospital to which the patient was admitted: The neurologic examination was the same as that recorded by us. Gynecologic examination revealed a soft cervix and a uterus enlarged to the size of about a two months pregnancy. Because of the improbability of a normal labor and doubtful viability of the fetus, termination of the pregnancy was advised. A week after admission a therapeutic abortion was performed. Her convalescence was uneventful. Orthopedic treatment was given and after two and a half months the patient was discharged in a double upright brace.

Three months later, the patient was readmitted to the hospital because she was pregnant. Her last menstrual period had been just before she was discharged the first time. The paralysis showed very little improvement. For the same reasons as during her first admission, therapeutic abortion was again performed.

Our first patient developed poliomyelitis at the end of her pregnancy. She came to term, had a normal pregnancy and labor and gave birth to a normal baby. This is similar to the majority of cases reported in the literature. The second patient developed poliomyelitis about the middle of her pregnancy. She had a normal labor and gave birth to a normal premature infant by spontaneous delivery about six weeks before term. The third patient developed poliomyelitis early in her pregnancy—some time during the second month. A therapeutic abortion was performed at another hospital.

EFFECT ON PREGNANCY AND LABOR

Not much information is available on the effect of poliomyelitis on pregnancy and labor. Numerous cases of paraplegia (due to trauma, tumor and the like) complicating pregnancy have been reported in the literature, and a normal labor, frequently painless, has been the rule. These have been reviewed recently by

Five of these were normal and one had bilateral clubfoot (which in all likelihood was not due to poliomyelitis). One infant, delivered by cesarean section before the period of viability, showed no deformity. Another, delivered prematurely, died in forty-eight hours but showed no deformity. Two of our patients delivered normal infants. This gives a total of eight living newborn infants without paralysis; one stillbirth and one death soon after premature delivery were apparently not due to poliomyelitis.

Certain other cases reported in the literature suggest that intra-uterine infection may occur. The pertinent points in each report follow:

Potts⁸ reported the case of a man, aged 54, with weakness of both lower extremities and of the left arm and hand which was present since birth, according to the patient as well as his brother and cousin (a physician). The mother was well during her pregnancy except for a fall about the fourth month, which con-

TABLE 2.—Eight Cases Previously Reported

|---|---------------------|--------------------|----------------------|--|-----------------------------|---|
| Schell, J. T.: New York M. J. 53: 637, 1906..... | Second | 7 | .. | Both lower extremities | Normal term | Normal |
| Renault and Martingay: Bull. et mém. Soc. méd. d. hôp. de Paris 31: 344, 1911 | Third | 5 | 23 | Both lower extremities | Normal term | Normal |
| Miller, N. P.: J. Michigan M. Soc. 23: 58, 1924... | Third | 3 | .. | Both lower extremities | Normal term | Bilateral clubfoot, not poliomyelitis |
| Miller, 1924 | First | 5 | .. | Left lower (cystitis) | Cesarean premature (6 mos.) | Dead (no deformity) |
| Hornung, R., and Creutzfeldt, N. J.: Deutsche med. Wehnschr. 56: 1470, 1920 | First | 8 | 20 | Landry's ascending type with respiratory involvement | Cesarean | Normal |
| McGoogan, ⁹ 1932 | First | 3 | 24 | Right lower extremity | Normal term | Normal |
| McGoogan, 1932 | Second | 3 | 32 | Hip muscles and bilateral abdominal muscles | Normal term | Normal |
| McGoogan, 1932 | First | 3 | 24 | Both lower extremities and right upper extremity | Normal premature (8 mos.) | Premature; died in 48 hours; no deformity |

McGoogan⁹ and need no further comment here. Williams⁶ stated that in women with spinal paraplegias the course of pregnancy is usually uncomplicated, and labor is easy and comparatively painless. Good⁷ found that transection of the spinal cord of a pregnant guinea-pig did not interfere with the normal contraction of the uterus following cesarean section.

There are eight cases of poliomyelitis reported in the literature with satisfactory data concerning pregnancy and labor (table 2). In five, delivery was spontaneous and normal at term. One patient had a premature normal labor. Two had cesarean section performed, one because the mother had an ascending paralysis involving the respiratory muscles. Two of our patients delivered normally, one at term and the other six weeks before term. From these data we feel that uncomplicated poliomyelitis (excluding respiratory paralysis) is not an indication for the interruption of pregnancy and that labor will not be affected adversely.

EFFECT ON THE NEW-BORN

In the literature there are reports of eight infants born of mothers with paralytic poliomyelitis (table 2).

6. Williams, J. W.: Obstetrics, ed. 4, New York, D. Appleton & Co., 1920.

7. Good, F. L.: Pregnancy and Labor Complicated by Diseases and Injuries of the Spinal Cord, J. A. M. A. 83: 416 (Aug. 9) 1924.

finer her to bed for several weeks. The patient had a 4 plus Wassermann reaction of the blood and spinal fluid. The patient died and from the autopsy the following anatomic diagnoses were made: meningovascular syphilis, arteriosclerosis and old poliomyelitis. Potts stated that there is no doubt that the patient had poliomyelitis, but it is known that syphilis may cause atrophic paralysis.

McCarthy⁹ reported a case of a man, aged 32, who had a left clubfoot, atrophy of the muscles of the limbs and contractures of the hands. The mother had been well during her pregnancy. The patient stated that he was born deformed. Autopsy revealed anterior poliomyelitis of the cervical and lumbar segments of the cord and interstitial neuritis following secondary degeneration of the peripheral nerves.

Lamy's¹⁰ case is that of a man, aged 43, with paralysis of the right leg, which he stated was present since infancy. The man died of carcinoma of the intestine. Autopsy revealed a cortical encephalitis of the left side and marked atrophy of the anterior horn cells in the lumbosacral segment of the cord.

8. Potts, C. S.: Intra-Uterine Poliomyelitis, Arch. Neurol. & Psychiat. 21: 268 (Feb.) 1929.

9. McCarthy, D. J.: Report of a Case of Prenatal Poliomyelitis, Rep. Henry Phipps Inst. 5: 437, 1907-1908.

10. Lamy, H.: Sur un cas d'encéphalite corticale et de poliomyélite antérieure associées, Rev. neurol. 2: 313, 1894.

Fritsch¹¹ observed a patient, aged 11 months, who was born by breech delivery without medical assistance. The paralysis of all the extremities was reported present at birth. By careful electrical studies of the involved muscles and in view of the symmetry of the muscle hypoplasia (and cord lesion), Fritsch concluded that the diagnosis was poliomyelitis.

Batten¹² observed his patient for the first time at 2 years of age. The mother had been well during her pregnancy. Delivery was normal and lasted only twenty minutes. Shortly after delivery, the infant fell from the bed to the floor. When examined at 2 years of age, the patient had weakness of the right arm, which, according to the history, was present at birth. There was weakness of both legs, which was noticed at 1 year of age, when the child began to walk. At 8 years of age the child died of diphtheria. Autopsy revealed changes due to poliomyelitis throughout the cord.

None of these cases established intra-uterine infection with certainty. In no instance was poliomyelitis diagnosed in the mother during pregnancy. In the first case (Potts) there was a complicating trauma and a syphilitic infection. The history of paralysis at birth in the first three cases was obtained from the patient when he had attained adult life. Data were not available from the attending obstetrician. Without an autopsy in Fritsch's case, injury to the cord (rapid breech delivery) cannot be ruled out. Batten's patient had poliomyelitis, but the time of onset is not certain.

Poliomyelitis may occur early in life. Lewis¹³ observed an infant who developed symptoms at 9 days of age and paralysis of one leg three days later. The mother had developed paralysis of one leg on the fifth day post partum. Finkelstein¹⁴ mentioned a case occurring in an infant, aged 12 days. Seven cases in infants under 1 month of age were reported in New York City in 1916.¹⁵ The occurrence of poliomyelitis during the first few months of life is not unusual.¹⁶ It is difficult to exclude infection in early infancy in any of the cases in which the disease is diagnosed later in infancy or childhood.

COMMENT AND SUMMARY

Probably poliomyelitis complicating pregnancy is a more frequent occurrence than one would assume from a review of the literature. Only eight cases have been reported. We observed three cases in one year during which time 1,010 patients with poliomyelitis were admitted to the hospital. Fifteen of these were women over 19 years of age. Contrary to the opinions expressed by other observers,⁸ the disease may occur early in pregnancy. As shown in table 2, half of the reported cases occurred during the third month. One of our patients was approximately six weeks pregnant when poliomyelitis developed. The reporting of more cases would help the obstetrician greatly in solving the problems that arise when poliomyelitis occurs. From analogy with other paralytic conditions and from the reported cases of poliomyelitis, it appears that pregnancy and labor will not be affected adversely. In no

instance has a mother in whom poliomyelitis developed during pregnancy transmitted the disease to her offspring.

There are cases reported in the literature in which the mother was essentially well during her pregnancy, and there was paralysis, presumably due to poliomyelitis, present in the new-born. In each of these cases either the data are not sufficiently complete or there is some factor which does not permit the acceptance of intra-uterine infection.

531 East Lincoln Avenue—Foot of East Sixteenth Street.

HYPOPROTEINEMIA PROBABLY DUE TO DEFICIENT FORMATION OF PLASMA PROTEINS

A STUDY OF ONE CASE

WALTER K. MYERS, M.D.

AND

F. H. L. TAYLOR, PH.D.

BOSTON

Attention has been repeatedly called to the association of hypoproteinemia with edema. Recently, Peters and Van Slyke¹ summarized the existing information. Hypoproteinemia has been observed repeatedly as a result of excessive loss of protein, decreased consumption of nitrogenous foodstuffs, and increased protein wastage. We are presenting a case with low plasma proteins and with edema which does not appear to be due to any one of these three causes.

A man, aged 51, Irish born, was admitted to the hospital because of edema of the genitalia and lower extremities. He had been treated for six months at the age of 4 years for "dropsy," which disappeared during that period of observation. For many years there was a slight but constant edema of the feet and ankles. The abdomen had been large since early childhood. Ten years before entry, a brownish discoloration, which was followed by some induration, appeared over the anterior surfaces of the lower legs. The swelling of the feet and ankles increased slowly, extending over the lower legs during the past five years. This swelling did not subside with rest in bed. The swelling extended finally, during the three months before admission, over the thighs and to the genitalia. It gradually became more marked until the time of admission to the hospital.

The family history was noncontributory. The past history was entirely negative except for painful, stiff noninflamed joints, until the age of 20 and the consumption of about 1½ pints of whisky daily for about twenty years, until four years previous to admission.

The patient was observed in the hospital for eleven months, and during this time he was afebrile. The pulse rate and the respiratory rate remained normal. On entry, the weight was 55 Kg.; the height was 162.5 cm. He was in no discomfort, mentally alert, and quite cooperative. The skin over the tibias had a brownish pigmentation and showed a brawny induration. There was considerable tense pitting edema of the feet, legs, thighs and genitalia. There was no clubbing of the fingers. The mucous membranes were of good color. There was no enlargement of the lymph nodes. The bony framework was normal. There were no tender areas in the skull. The pupils were equal and regular and reacted to light and in accommodation. The examination of the fundi revealed no abnormalities. The thyroid gland was barely palpable and revealed no nodules or irregularities. The chest was well formed and symmetrical. The lungs were normal. The heart was not

enlarged to percussion, which was confirmed by roentgen examination. The heart sounds were well heard; no murmurs were detected. The pulses were equal, regular, synchronous and of good volume. The systolic blood pressure was 110 mm. of mercury; the diastolic, 70 mm. The abdomen was symmetrically enlarged; the abdominal wall was tense. There was no tenderness or spasm. No dilated veins were seen. No masses nor viscera could be detected. Shifting dullness and fluid wave were absent. Except for edema, the external genitalia were normal. Rectal examination revealed no abnormalities. The neurologic examination was entirely within physiologic limits.

The edema decreased during the first two weeks while the patient rested in bed and the fluid intake was restricted. Slight pitting edema over the tibiae persisted throughout the eleven months of observation and was present at the time of discharge.

The Kahn reaction of the blood was negative.

Examination of the urine was repeatedly negative. No albumin was demonstrated. The phenolsulphonphthalein excretion following intravenous administration was 40 per cent in the first hour and 10 per cent in the second hour. The dilution-concentration test showed a specific gravity range of from 1.014 to 1.024. These studies did not indicate an impairment of renal function.

On entry, the hemoglobin was 90 per cent (Sahli) and the erythrocytes were 4,950,000 per cubic millimeter. There was no significant change in these determinations during the period of observation. The leukocytes varied between 3,900 and 7,450

A roentgen examination following a barium enema revealed only a spastic colon; the arteries of the legs showed deposits of a moderate amount of calcium.

Fasting gastric contents revealed no free acid. After the administration of histamine the gastric juice contained 36.0 units of free acid. The pepsin content of both specimens was normal.

The basal metabolic rate was +9.0 per cent.

Serum calcium and phosphorus were found to be 7.9 mg. and 3.6 mg. per hundred cubic centimeters, respectively, values which are consistent with the lowered plasma proteins. The cholesterol of the blood was in the lower limits of normal, 89 and 96 mg. per hundred cubic centimeters on two occasions, several months apart. Blood chlorides as sodium chloride were within the range of normal, 462 mg. per hundred cubic centimeters. The colloidal osmotic pressure of the serum was found to be 15 cm. of water. The plasma protein, as determined by the Kjeldahl method, on oxalated plasma, was 3.6 Gm. per hundred cubic centimeters, and the albumin-globulin ratio determined by fractional precipitation with a solution of potassium phosphates was 60/40. The ingestion of a diet containing 180 Gm. of protein daily for eight weeks did not alter in the least the plasma proteins or the albumin-globulin ratio. Unfortunately, a determination of the fibrinogen was not made.

Studies of the nitrogen metabolism were also made. The partition of the blood and nonprotein nitrogen of the urine and the nitrogen of the feces were determined when the daily

per cubic millimeter. The differential counts were always essentially normal. The sedimentation rate of the red blood cells was abnormally slow, less than 1 mm. per minute.

Studies of liver function were made. The venous blood sugar curve after the administration of 1 Gm. of dextrose per kilogram of body weight showed no abnormal tolerance; the blood sugar attained a maximum of 153 mg. per hundred cubic centimeters in thirty minutes from a fasting level of 78 mg. and a minimum of 70 mg. in two hours. Similar studies with levulose, 1 Gm. for each 1.5 Kg. of body weight, revealed a rise of 40 mg. from a fasting level of 73 mg. per hundred cubic centimeters; this pointed toward a decreased tolerance, as a rise of 30 mg. from the fasting level is considered to be the maximum normal rise. A similar decrease in tolerance for galactose following the ingestion of 40 Gm. was indicated by the urinary excretion of 4 Gm. in the five-hour period; the maximum normal excretion expected is 3 Gm. As is to be expected normally, there was no retention of bromsulphalein thirty minutes after intravenous injection. The icteric index was 2, which is abnormally low and suggests that pigment formation is impaired. Likewise, the bilirubin was less than 1 mg. per hundred cubic centimeters.

Amyloid disease was not indicated by the removal of only 29 per cent of congo red from the serum in one hour.

The investigation of the cardiovascular system revealed normal blood gases, and the circulation time and the cardiac output were within the limits of normal.

Serologic and chemical studies of the cerebrospinal fluid gave normal results. The total proteins were 11 mg. per hundred cubic centimeters; the chlorides were 702 mg. per hundred centimeters as sodium chloride.

diet contained 60 Gm. of protein and again when the protein intake was 180 Gm. daily. During the period of the 60 Gm. protein intake, pepsin, 10 Gm. daily for a period of six weeks and later trypsin, in similar amounts for two weeks, were given without producing any significant alteration in the nitrogen metabolism. The stools showed no measurable increase in nitrogen between the low and the high protein diet. The loss of nitrogen in the stools was not more than from 1 to 2 Gm. a day.

The accompanying table gives the values for the various constituents of the nitrogen partition of the blood and urine. The values termed the normal range indicate the limits of variation obtained by the methods employed in this investigation.

The amino-acid nitrogen of the blood varied between 6.51 and 8.14 mg. per hundred cubic centimeters, remaining above the normal level constantly. The urinary ammonia nitrogen likewise remained elevated, varying between 6.28 and 10.0 per hundred cubic centimeters of the total nonprotein nitrogen. The changes in the remaining nitrogen partitions of the blood and urine were such as would be expected to follow a high and low protein diet.

During the entire period of observation, the plasma proteins varied between 3.4 and 4.0 Gm. per hundred cubic centimeters, considerably below the normal level. The protein deficiency was proportionately distributed between the albumin and the globulin fractions.

COMMENT

It appears that the patient had no difficulty in the digestion and absorption of protein, as evidenced by his urinary and fecal nitrogen excretion and by the effect of changes in diet as reflected in the nonprotein

nitrogen partition of the blood. There is no evidence suggestive of renal disease or of increased protein wastage.

This degree of hypoproteinemia with a normal albumin-globulin relationship is unusual. Such inorganic constituents as have been determined in the patient, chlorides, calcium and phosphorus, do not indicate an alteration in the inorganic constituents of the blood. The cholesterol values are in the lower range of normal. The essential abnormality seems to be in the mechanism of synthesis of plasma proteins. This is emphasized by the failure of protein feeding to influence the level of the plasma proteins.

The origin of the plasma proteins is poorly understood. The weight of the evidence at hand indicates that fibrinogen is formed in the liver and that the liver, intestinal wall and the blood-forming organs are probable sites of origin for other plasma proteins.² It is of interest to note that in this patient a disturbance in liver function is suggested by the somewhat decreased galactose and levulose tolerances and by the elevated blood amino-acid nitrogen. It is conceivable that the defective formation of plasma proteins here is due to altered liver function.

SUMMARY

The hypoproteinemia in a patient with chronic edema, low plasma proteins and reduced colloid osmotic pressure was uninfluenced by protein feeding. The observations made seem to indicate a deficiency in the formation of plasma proteins.

ERYTHREMIA

A THERAPEUTIC SUGGESTION

ROGER S. MORRIS, M.D.

CINCINNATI

Erythremia (polycythemia vera) is generally considered a primary disease of the hematopoietic system, of unknown etiology. Despite the great increase in the number of the erythrocytes in this disease, immature cells in the peripheral blood present evidence of increased activity of the bone marrow, an appearance usually associated with anemia. The occurrence of polychromatophilia, of normoblasts and of myelocytes in the blood cannot be explained satisfactorily in any other way.

Studies have shown that the stomach of man and of dogs secretes a substance which may be recovered in a form suitable for intramuscular injection and which is a powerful stimulant of marrow activity in pernicious anemia.¹ From the stomach contents of swine and cattle, obtained immediately after slaughtering, a similar, probably identical, substance has been obtained. This substance is dialyzable through collodion and withstands esterification, properties that would seem to remove it from the enzymes. It is probably a hormone, for which the name "addisin" has been proposed.

As pernicious anemia appears to be due to a lack of secretion of addisin, it seemed theoretically possible that erythremia may be the result of hypersecretion of addisin or of hypersusceptibility of the marrow to

it.² A similar hormone theory has been advanced by Hurst³ and by Tuchfeld,⁴ independently.

In a patient with erythremia, having 8.9 million red cells, addisin derived from 1,250 cc. of the gastric contents of swine was injected intramuscularly. On the fifth day following the injection, the reticulocytes, which had been in the neighborhood of 1 per cent, rose to 2.5 per cent, or from 89,000 to 212,000 per cubic millimeter. Coincident with this reaction, an occasional normoblast was found in the blood and erythrocytes containing minute nuclear particles, which were absent or nearly so (270 per cubic millimeter), rose to a maximum of 14,700 per cubic millimeter on the sixth day, followed by a rapid fall. On the ninth day after the injection, a differential count showed 1 per cent myelocytes. These results indicate clearly a response of the bone marrow to stimulation by addisin, despite the polycythemia.

Another fact in support of this theory was presented by the same patient. He had suffered from duodenal ulcer and, on advice of his physician, he passed a

stomach tube and washed his stomach three or four evenings a week for a period of six months. During this time, without other treatment, the red cells decreased steadily from 10.0 to 5.3 million. The lavage was then discontinued, and the count gradually increased to 10.2 million at the end of five months. It seems quite possible that the improvement noted was due to mechanical removal of an appreciable quantity of addisin with a corresponding decrease in stimulation of the bone marrow.

Examination of the sources of hematopoietic substances effective in pernicious anemia discloses a high purine content (liver, kidney, stomach, nucleic acid). Should the diseases pernicious anemia and erythremia represent in reality an addisinism and hyperaddisinism, as seems theoretically possible (like myxedema and hyperthyroidism, for example), there would seem to be the possibility of controlling erythremia by means of dietary measures. For this purpose, a low purine diet continued over a long period of time, with careful study of the blood, is suggested.

As erythremia is a comparatively rare disease, this suggested treatment cannot be observed in any one clinic

in a sufficiently large number of patients to be of value. I have started one patient on this diet and have suggested its trial in two others. This note is published in the hope that the plan may appeal to others as worthy of trial, so that evidence pro or con may be accumulated.

TUBERCULOUS FISTULA IN ANO

CLEMENT L. MARTIN, M.D.

CHICAGO

For years it has been taught by various clinicians and writers on tuberculosis that a tuberculous fistula should not be operated on, that, after operation, it is more apt than not to recur, and that if it remains healed the pulmonary disease, if latent, is often activated and, if active, is frequently made worse. Although proctologists for a number of years have operated on tuberculous anal fistulas and obtained favorable results, the beliefs enumerated are widely held and perpetuated in recent publications. It is the repetition of traditional error. One might almost suspect some of the ideas of having survived the era of the humeral theory, when it was feared to stop a discharge in one place lest this dam back the humors, which would break out anew elsewhere.

Tuberculous fistulas will heal after adequate operation if reasonable care is given to the pulmonary disease. For several years I have been performing fistulectomy on patients having tuberculosis, in many cases even in the advanced stages. The removal of a suppurative focus benefits the patient; this is especially true if the area of suppuration is fairly large, as it often is in these patients. Toxemia is reduced and the patient is made more comfortable and rests better. The importance of the elimination of an area of suppuration in an already handicapped patient needs no emphasis. And, if brief, fistulectomy carries out one of the cardinal tenets of present day therapy in the disease; i. e., the elimination of tuberculous or nontuberculous complications to focus healing ability on the pulmonary lesion.

These convictions have been reached over a period of several years while I was caring for patients at the Chicago Municipal Tuberculosis Sanitarium. Recently, a study was made of seventy-five fistulectomies which I have performed in the last five years. Some of the facts brought out in this investigation are of interest.

AGE AND SEX

The ages of the patients ranged from 13 to 74 years. The greatest incidence was in patients aged from 20 to 40 years; the next highest incidence was in the following decade. Only four were under 20 years of age. The age incidence approximated that of pulmonary tuberculosis. There were twenty-two women and fifty-three men, 30 and 70 per cent, respectively. The greater incidence in males is common in fistula in ano of any type; nontuberculous fistula is much more common in males.

PULMONARY DISEASE

All the patients had pulmonary tuberculosis and with two exceptions such disease was active. On admission, twenty-eight were classified moderately advanced B cases and twenty-six far advanced B cases; twenty-one

fell among the other classifications. On discharge, the classification was more diverse; more patients were included in the moderately advanced A and B groups and in the far advanced A and B groups, and seven were classified as far advanced C cases, although no cases in the C group were admitted.

TYPE OF PATIENTS

The patients admitted to the sanatorium are not chiefly the ones with old chronic fibroid lesions. The pulmonary types are a mixture of the exudative and proliferative disease and not the progressive chronic proliferative type chiefly seen in custodial institutions. The former are the types seen in active practice, requiring active therapy or requiring care in sanatoriums conducted on a modern treatment basis. Admission to the sanatorium is based chiefly on the tuberculous lesion being sufficiently limited or early, so that improvement or an arrested process is possible with well regulated institutional care. In a word, the majority of the patients are of the sort seen in general practice.

LENGTH OF TIME IN SANATORIUM

The yearly admission is about 2,000 and the average enrolment is 1,225. The average stay in the hospital varies from year to year; in the last five years it has varied from 344.1 days to 276.6 days. One third of the seventy-five fistulectomy cases were hospitalized less than a year. The time at the sanatorium of the whole group varied from 60 to 874 days, the average being 252 days.

DURATION OF FISTULA

Sixty-three patients (84 per cent) had pulmonary tuberculosis from a few weeks to thirteen years before the fistula occurred; ten patients (13.3 per cent) had the fistula before a diagnosis of pulmonary tuberculosis was made. It had existed in these cases from twenty-one years to two months: One had the fistula twenty-one years; one, six years; one, five years; two, four years; one, three years; one, one year; two, six months, and one, two months. Tuberculous granulation tissue was not found in any fistula over five years old. Whether the process was originally tuberculous cannot be determined. Of two four year old fistulas, one was tuberculous, the other not; a three year fistula was tuberculous, as was one a year old; two six months old fistulas were nontuberculous, and one two months old was tuberculous. Much has been written about primary tuberculous anal fistula. With such variation in duration and type in our cases, generalizations are of little moment. It is rare in our experience.

PATHOLOGIC STUDIES

A diagnosis of tuberculous fistula is based on the finding of tuberculous granulation tissue on microscopic examination. Fifty-six per cent of the cases in this series showed such tissue on the usual pathologic examination; a further investigation was made of tissue from the last nineteen fistulectomies performed in 1932. Between 200 and 300 sections were made serially of each specimen and all examined for characteristic granulation tissue. Two cases (16 per cent) previously reported negative were found to present tuberculous tissue. If this average prevailed in the preceding four years, and such an assumption is reasonable, the total incidence of tuberculous fistula in patients having pulmonary tuberculosis in our series is 72 per cent.

The tissue submitted to the laboratory is not the fibrous wall of the collapsed abscess cavity or infected

Read before the American Proctologic Society, Chicago, June 12, 1933.

From the City of Chicago Municipal Tuberculosis Sanitarium and the Loyola University School of Medicine.

tract but the gelatinous granulation tissue that lines the cavities or tracts. Giant cells, tubercles and other characteristic structures are found in this tissue when the fibrous wall shows nothing significant. After the fistula has been opened, these granulations are simply scraped out with knife or gauze and placed at once in physiologic solution of sodium chloride and sent to the laboratory. Care in providing the pathologist with live granulation tissue is important; however, this cannot always be done, for in some tracts there is even very little necrotic granulation tissue to be obtained. In two cases, clinically tuberculous, only repeated laboratory investigations demonstrated tuberculous tissue.

THE PATHOLOGIC DIAGNOSIS OF RECTAL FISTULAS

H. C. Sweaney says:

The diagnosis of tuberculosis in fistulas of the anus and rectum depends entirely on the histopathological findings, because the gross, the clinical, and the bacteriological findings are indefinite or of no value. The histopathological diagnosis depends upon the time honored presence of tuberculous granulation tissue [fibroblasts, capillaries, fibrin, lymphocytes, etc.] with the Langhans type of giant cell; characteristic tubercle formation with necrotic center; fibroblastic capsule and mononuclear and lymphocytic infiltration.

Inasmuch as the microscopic diagnosis of tissue from rectal fistulas in our institution has run less than 60 per cent positive for tuberculosis in the last five years [exclusive of 1932] it is pertinent to make an inquiry into the causes of such low findings, especially since the great majority are considered to be, and most likely are tuberculous. It must not be inferred from this, however, that all anal fistulas are tuberculous. There is no reason why other infectious agents may not cause ulcers in this region.

Like most analytical procedures the problem may be considered from the standpoint of the sampling, and the examination.

The "sampling" or taking of specimens, depends upon the individual clinician and the character of the fistula. He may take only a small tag of tissue or dissect out the entire tract. In the complete dissection only superficial tissue may be removed or the entire layer of granulation tissue may be taken. In removing sloughs or tags of tissue there is the greatest likelihood of error, and as I review our sections, it is this type in which we have had most of our negative findings. The tissue is usually necrotic with nothing left but the original stroma outlining the intestinal glands at one end of the tract and a few extinct capillaries in the old granulation tissue. The staining is usually a pale blue, showing that there is only acid-bearing tissue present. Even the usual pink of tuberculous caseation is absent. Here one may find the hull of an old giant cell and characteristic granulation tissue, but frequently the disintegrating intestinal glands will resemble a giant cell, so it is risky to make a diagnosis in such findings even though one may have the feeling that it is tuberculous. In such tissue there would be little gained in making serial sections, because the tissue is uniformly necrotic. It is always advantageous to take some live granulation tissue for section or remove the whole ulcer, in which cases the burden falls on the pathologist. Where there has been live granulation, the diagnosis has usually been easy in our routine examination, which consists in the mounting of 3-6 paraffin sections taken at intervals. In negative cases, especially where the tissue is suspicious, complete serial sections are indicated.

Apart from the sampling and the conditions just referred to, however, there are times when the findings—either negative or positive—may not be accurate.

On the one hand, granulation tissue of any chronic nature, may simulate tuberculosis. Even the giant cells may be found. Syphilis is one of several such chronic granulomas. The giant cell is a foreign body reaction—a reaction against an indigestible substance whether it is wax, wood, caseum, cholesterol or other such inert material. As some such substances may be present, there is always the possibility, although rarely, of confusing them with tuberculosis. There are, however, peculiar

characteristics of the giant cells of tuberculosis that are rather definite—their fullness, the pink centers, the vigorous cells arranged in a semicircle, etc.

On the other hand there may be tuberculous fistulas and ulcers that do not reveal a single giant cell even on serial section. Whether this is due to the type of bacillus, to the reaction of the host, or to an overgrowth of secondary organisms, is problematical. There is no doubt but secondary overgrowth will change the picture to a marked degree. I have serially sectioned ulcers that have only shown the characteristics of subacute abscess that were undoubtedly tuberculous, because the gross characteristics, the surrounding ulcers, and all other factors were typically tuberculous. I have seen hyperplastic tubercles showing only fibroblasts, monocytes, etc., without any giant cells at all. To make a diagnosis, however, on characteristic granulation tissue alone is risky, because I have seen chronic infections with Friedländer's bacillus simulate tuberculous granulation tissue, except there were no giant cells.

With careful, repeated, or complete sampling, with serial sections, and with careful study, however, over 75 per cent in tuberculous patients should be found tuberculous. No doubt, all but an insignificant minority are tuberculous.

INCIDENCE OF TUBERCULOUS FISTULA

Seven per cent of the patients at the Municipal Tuberculosis Sanitarium have anal fistula. Only a very small number of the anal fistulas in my private practice are demonstrably tuberculous. The number varies from year to year, but from 3 to 5 per cent is the maximum. Consequently, I cannot think that an anal fistula is a common indication of pulmonary tuberculosis. Most of the anal fistulas in the tuberculous patients are tuberculous, but very few of all anal fistulas are tuberculous in this portion of the United States. However, Miles reported two years ago that about 14 per cent of anal fistulas are tuberculous.¹ The material of some foreign authors probably differs from ours and justifies other conclusions. There is no excuse for foregoing a careful chest examination of the patient having a fistula, even if the incidence here is relatively low. Error is possible even after careful investigation, as has been shown. It is courted in the exceptional case; that is, in from 3 to 5 per cent if physical examination is indifferent or incomplete. Medico-actuarial statistics show that a sufficient number of patients who have or have had anal fistula do develop pulmonary tuberculosis to compel insurance companies to inquire carefully into the character of fistula in their clients, especially if they are 15 per cent or more underweight.² Although not many of all fistulas are tuberculous, the relatively high incidence of it in the tuberculous must be considered.

Symptoms depend on the extent and character of the infected tract. If it is short and rather superficial, a thin purulent discharge only may be present. When it is larger and deeper and more tissue is involved, toxemia, local discomfort or soreness, and a free purulent discharge may exist. When the external orifice becomes blocked, pain and swelling develop. In a blind internal fistula (internal sinus) this occurs when the internal orifice is blocked. Some fairly large or large and deep tuberculous abscesses develop without much pain, but it seems to me that the painlessness of perianal and perirectal suppuration in the tuberculous patient has been overemphasized. They are generally painful in my experience.

The diagnosis is important before an effective operation can be done. An anal fistula usually arises from a

1. Miles, W. E.: *Anorectal Fistulas: Their Classification, Pathology and Treatment*, Practitioner, 126: 501-536 (May) 1931.
2. Fansler, W. A.: *The Relationship of Tuberculosis to Fistula in Ano*, J. A. M. A. 85: 671 (Aug. 29) 1925.

crypt infection. The crypt becomes infected, the inflammatory process extends through the bowel wall and an abscess forms. This may rupture within the bowel or on the skin, or the abscess may be incised through the skin. Thus an infected tract is left: a complete fistula with both internal and external openings, a blind internal fistula (more accurately a perianal or internal sinus) with only an internal orifice or a blind external fistula (external sinus) with only an external orifice. Fistula may, rarely, follow trauma, e. g., a kick or fall on the buttocks, and a subcutaneous fistula may develop from a thrombotic external hemorrhoid; a tuberculous coccyx or sacrum may cause a perianal fistula, or it may arise from a stricture a few inches up in the rectum. A periprostic or suburethral abscess may drain through the perineum. But the primary infection in the vast majority of cases is in a crypt, at the junction of the skin with the mucosa; the pathologic sequence is that already stated. This deserves emphasis and it is of great importance to keep this in mind when looking for the internal opening. Success depends on laying open the whole infected tract or tracts, particularly the internal orifice. The latter is nearly always in a crypt. A flexible silver probe, made by "beading" 19 and 21 gage silver wire by holding the ends a moment in the flame of a Bunsen burner, is very satisfactory for exploring the fistula. If the internal orifice cannot be found with this, one of the dyes, gentian violet or methylene blue, may be used. I prefer bismuth paste, 1 part of bismuth subnitrate to 2 parts of petrolatum (Beck's paste), as it is cleaner and just as effective. In a few instances it is helpful to inject the tract with iodized poppy-seed oil or bismuth paste and have a roentgenogram made. This procedure is overdone: it is only rarely helpful or necessary. If the examination is painful, it is advisable to wait at times until the patient has been given a local anesthetic before the diagnosis is completed; in this case, fistulectomy is done under the same anesthesia. In any event, an accurate diagnosis is essential before operation.

CHARACTERISTICS OF TUBERCULOUS FISTULA

A fistula is considered grossly tuberculous when the skin orifice is large or gaping, the edges are undermined and cyanotic and the tract is much more patulous, "eaten out," than in the ordinary type.

INDICATIONS FOR OPERATION

Some small anal fistulas give very little trouble to the patient and may be safely left alone. It is not my experience that any great number heal spontaneously, as some hold, but a small fistula does not demand operation. I see relatively few of these. Most of my patients have a fistula of moderate size, a fair proportion of large size, and these are causing pain or discomfort. Most of them contain enough pus to act as a serious focus of infection.

Certainly a fistulectomy is merely an incident in the management of the pulmonary disease. In some terminal cases the patients are made much more comfortable by the operation. It may be inadvisable for a time, in a moderately advanced case, because of the activity of the disease in the lungs or elsewhere. Decision is based on a consideration of all the aspects of the case. Briefly, a perianal abscess requires incision and drainage as soon as it is diagnosed. The opening is kept patent by swabbing the tract daily or two or three times a week. Adequate drainage is maintained and thus the formation of new tracts is avoided. Some cases heal without further treatment. Fistulectomy is

performed when the infected tract persists and when the patient's condition permits. In Fansler's³ series of 101 cases, 90 per cent healed after fistulectomy, whereas 65 per cent of the patients not operated on (twenty-three cases) were unimproved or died.

ANESTHESIA

In most cases the injection of 35 cc. of a 1 per cent solution of procaine hydrochloride in the sacral canal and 10 cc. in each second sacral foramen is used. In the unusual instance in which this did not afford complete anesthesia, the third or fourth or both foramina on the incompletely anesthetized side were injected. Caudal block and some perianal infiltration with a 0.5 per cent solution of procaine hydrochloride was done in cases in which the time could not be taken with the procedure described. Fifteen patients were given a low spinal analgesia, 50 mg. of procaine crystals dissolved in cerebrospinal fluid or 1 cc. of a proprietary procaine mixture being used. I prefer the transsacral and caudal anesthesia in this work, but there were no unfavorable reactions with the spinal analgesia; they are not to be expected with the small amount of drug used.

Sodium amytal, $1\frac{1}{2}$ grains (0.1 Gm.), is given the night before operation, 3 grains (0.2 Gm.), one and a half hours preoperatively and one-sixth grain (0.01 Gm.) of morphine sulphate fifteen minutes preoperatively.

OPERATION

A barium or bismuth paste was frequently although not usually injected through the external orifice to identify the tract and internal orifice. Often this is not necessary. Filiform bougies or flexible wire probes, gage 19 to 21, may suffice. Accurate identification of the internal orifice is essential; the fistula will recur or, what more often happens in these cases, the wound will not entirely heal if the internal orifice remains. If there is no internal opening, that is, if the fistula is incomplete, only confusion, if nothing worse, is caused by making one. This can readily be done with the stiff wire probes used by many surgeons and found in many hospitals. There is no advantage in cutting the sphincter and to incise a normal crypt, even when the tract seems to end at this crypt. But in some cases the internal orifice has healed or inflammation has extended through the bowel wall at this crypt site. If there is a nodule of scar tissue in the crypt or the crypt is obviously deformed from previous inflammation, the incision should be extended through the sphincter to the crypt and the crypt excised. Chronically inflamed tissue at the upper extremity of a fistulectomy wound will delay or prevent healing in tuberculous cases.

When this work was started five years ago, the cautery was used as a routine. The thought was that the lymphatic and in back of this the fibrous tissue reaction was the barrier to the extension of tuberculosis here as elsewhere and that the knife would open up new channels for extension of the infection. Comparing results of operation by the two methods, scalpel or cautery, better results were had in the former. The radio knife was used in some cases. In the last three years the ordinary knife or scissors have been used; dissection is accurate and the wound heals satisfactorily afterward.

After the tract and its lateral extensions, if present, have been opened, it is wiped out with gauze to clean out debris and granulations; when the latter are quite adherent, they are cleaned off the fibrous tissue with the

scalpel. Overhanging skin edges are trimmed off, "unroofed" to provide for adequate drainage by converting the tract into a V shaped gutter. Hemostasis is secured and iodoform gauze is placed in the wound. Not all fistulas have a firm fibrous tissue wall; if they do, the wall is not scarified as in the usual fistulectomy; if they do not, care is taken to avoid undue traumatization of the tract when it is cleaned out.

If the orifices are eliminated and the tract is well and completely opened and given proper postoperative care, these wounds heal. Even if the fistulas are multiple and the tracts tortuous and extensive, as a number of these were, healing occurs.

RATE OF HEALING

Some wounds are completely healed in from two to three weeks. These are usually nontuberculous tracts or appear in patients with lung disease which is not very active. The wounds ordinarily heal slowly. The average rate is several times as long as in a nontuberculous patient. The majority of wounds are healed in four months, a number are not entirely healed before six months, and a few for a longer period. One coincident with pulmonary disease which was very active for a time healed slowly over a period of a year and a half. These wounds cannot be expected to heal as readily as a wound in a healthy subject; the patients have an exhausting disease; the reparative power of the tissue is less than normal. If one is certain that the operation has been adequately done, a complete repair may be confidently anticipated. Patients in the terminal stages are excepted. Ten patients died before their wounds were entirely healed, but except in two of these, wound healing was progressive, although the pulmonary disease was advancing. In eight cases healing was well advanced at the time of death. The wounds healed completely in 87 per cent of our cases.

POSTOPERATIVE REACTION

Sixteen patients (20.1 per cent) were made temporarily worse by the operation; that is, there were increased pulse rate, increased fever or the occurrence of fever in a previously afebrile patient, increased pulmonary disorder or other evidences of an unfavorable reaction, for periods of from a few days to two weeks. Very few had a marked reaction and these were practically all in large fistulas in advanced cases. Even in this group, the permanent results are good. No patient was made permanently worse by fistulectomy.

GAIN IN WEIGHT

No marked gain in weight occurs in some cases, but a gradual improvement generally follows. A gain of from 5 to 10 pounds (2.3 to 4.5 Kg.) was made in the majority within a six month period after operation; eight gained 15 pounds (6.8 Kg.), and four, 20 pounds (9 Kg.) in this time.

RESULTS OF OPERATION

It is a striking fact that the patient is usually made definitely more comfortable by the operation. The general improvement noted is undoubtedly due to (1) elimination of a focus of suppuration, and (2) increased relaxation and rest by the removal of a source of irritation or pain.

CONCLUSIONS

1. Because of a traditional belief that they should not be operated on, anal fistulas in tuberculous patients are often neglected.

2. In this series, 56 per cent of anal fistulas in fifty-five patients having pulmonary tuberculosis were proved tuberculous; 72 per cent of twenty cases in 1932 were proved tuberculous, by more detailed investigation. That something more than 72 per cent are tuberculous is probable. Seven per cent of all pulmonary tuberculosis cases at the Municipal Tuberculosis Sanitarium presented anal fistulas. Relatively few cases of anal fistula are tuberculous.

3. The diagnosis of tuberculosis in fistula of the anus and rectum in patients with pulmonary tuberculosis depends entirely on the histopathologic examination because the gross, the clinical and the bacteriologic results are indefinite or of no value.

4. In 87 per cent of the patients with pulmonary tuberculosis on whom anal fistulectomy was performed, healing was complete; the remaining 13 per cent were far advanced cases; despite this fact, healing was progressing in 10.4 per cent of these up to the time of death. This does not confirm the claim that these wounds do not heal satisfactorily.

5. In the tuberculous patient, a perianal abscess should be incised as soon as it is diagnosed. Drainage of the infected area must be maintained. If a sinus or fistula persists, it should be operated on as soon as the general condition permits.

OCCURRENCE OF THE BORDET-GENGOU BACILLUS

BJÖRN KRISTENSEN, M.D.
COPENHAGEN, DENMARK

In continuation of previous investigations¹ issued from the Danish State Serum Institute, I have carried out some systematic studies on the occurrence of the Bordet-Gengou bacillus.

Since 1916, this institute has employed the coughing-plate method introduced by Adolph H. Meyer for the bacteriologic diagnosis of whooping cough, and in Denmark this method is being used more and more.

Previously the results from a total of 2,811 suitable specimens have been compiled. In addition, I have examined 1,086 suitable specimens at the State Serum Institute during the period from Sept. 1, 1930, to March 1, 1931. All told, the material consists of 3,897 specimens, 2,144 of which came from pertussis patients. The results from these 2,144 examinations are given in table 1.

From the material of the serum institute it is difficult to say anything definite as to the occurrence of the Bordet-Gengou bacillus in the later stages of whooping cough because it is relatively seldom that specimens come from patients in these stages and also because it cannot with certainty be taken for granted that the data on the information of the stage of the disease in these cases are altogether correct. For these reasons, I have made a systematic examination on 109 children

From the State Serum Institute, Thorvald Madsen, M.D., Director.

who had whooping cough, letting them cough on a plate of Bordet-Gengou medium from two to three times a week for a considerable length of time. When the coughing ceased, I employed the following method for making cultures: With a sterile probe, bent to an angle of 130 degrees, I tried to obtain some secretion from as far down in the larynx as possible, taking precautions at the same time not to touch the mucous

TABLE 1.—Results from Examination of 2,144 Pertussis Patients

| | Number of Pertussis Patients | Number of Patients with Bordet-Gengou Bacillus | Frequency of Positive Bacillary Results |
|-------------------------------------|------------------------------|--|---|
| Catarrhal stage..... | 378 | 247 | 65.3% |
| Convulsive stage, 1st week..... | 887 | 486 | 54.8% |
| Convulsive stage, 2d week..... | 441 | 231 | 52.4% |
| Convulsive stage, 3d week..... | 210 | 84 | 40.0% |
| Convulsive stage, 4th week..... | 104 | 35 | 33.7% |
| Convulsive stage after 4th week.... | 174 | 13 | 7.5% |

membranes of the mouth and fauces. In every case, cultures were made from the posterior wall of the pharynx before inoculation from the larynx was undertaken. It was only in a few cases that cultures from the pharynx turned out to be positive. The material obtained with each probe was used for smear cultures in at least two dishes of the pertussis medium employed by the institute.

After practicing this technic for some time, I almost always succeeded in obtaining suitable smear cultures, which allowed an examination of the same number of isolated colonies as are usually found on a plate inoculated by coughing. Control tests showed that the presence of Bordet-Gengou bacilli can be demonstrated just about as often by cultivation from the larynx as with the cough-plate method.

The results obtained in the systematic examinations of these 109 children are given in table 2.

TABLE 2.—Results of Systemic Examination of One Hundred and Nine Children *

| | Number of Examinations | Number of Positive Results | Frequency of Positive Results, per Cent |
|-----------------------------------|------------------------|----------------------------|---|
| Convulsive stage, 1st week..... | 68 | 43 | 63.2 |
| Convulsive stage, 2d week..... | 65 | 22 | 33.8 |
| Convulsive stage, 3d week..... | 89 | 16 | 18.0 |
| Convulsive stage, 4th week..... | 93 | 4 | 4.3 |
| Convulsive stage, 5th week..... | 95 | 4 | 4.2 |
| Convulsive stage, 6th week..... | 72 | 0 | 0 |
| | 57 | 1 | 1.8 |
| | 52 | 1 | 1.9 |
| | 22 | 0 | 0 |
| | 20 | 1 | 5 |
| Convulsive stage, 11th week..... | 13 | 0 | 0 |
| Convulsive stage, 12th week..... | 7 | 0 | 0 |
| Convulsive stage, after 12th week | 22 | 0 | 0 |

* Total number of examinations, 675 on 109 children; that is, on an average, 6 examinations on each child.

As the children were examined more than once in the same week, the frequency of positive cultures is somewhat greater in proportion to the number of children than in proportion to the number of examinations (table 3).

If the data in regard to the 3,897 plates examined at the serum institute by different observers since the procedure was initiated are collected, a curve of the duration of carriage of the organism could be drawn. However, such a curve would be unreliable because too few examinations were made after the fourth week and

because the examinations were made by different observers.

I have therefore constructed a curve based on my own material, which consists of the examinations on the 109 children previously referred to and on the 1,086 samples examined by me in the diagnosis station.

In Denmark, pertussis patients are quarantined during the first four weeks of the convulsive stage.

From my bacteriologic studies it is to be expected that infection may be transmitted from the patients late in the course of the disease. Still, it is a question whether this actually happens often enough to extend the quarantine. To elucidate this question, I have gathered the practical experiences of the past fifteen years in Denmark concerning the infectivity of whooping cough after the fourth week of the convulsive

TABLE 3.—Percentage of Positive Results by Weeks

| | |
|---|------|
| In the 5th week B.-G. bacilli were found in 4 out of 57 children | 7.0% |
| In the 6th week B.-G. bacilli were found in 0 out of 47 children | 0% |
| In the 7th week B.-G. bacilli were found in 1 out of 33 children | 3.0% |
| In the 8th week B.-G. bacilli were found in 1 out of 30 children | 3.3% |
| In the 9th week B.-G. bacilli were found in 0 out of 13 children | 0% |
| In the 10th week B.-G. bacilli were found in 1 out of 11 children | 9.1% |

stage. It turns out to be a very rare occurrence in schools, hospitals, nurseries, asylums or any institution that a pertussis patient communicates the infection after the quarantine is discontinued.

The question whether there are chronic carriers of whooping cough has not been investigated before on a scale sufficient to allow of any conclusions. No comprehensive systematic investigation into this question has been published before, and those few reports of the finding of the Bordet-Gengou bacillus in persons who have no whooping cough have all been rather doubtful. Therefore, I have examined 500 healthy

Relation between stage of the disease and percentage of positive results. C.S., catarrhal stage.

persons who did not cough and who had not been in contact with any pertussis patients in the infectious stage; these examinations were made with cultures from the pharynx and from the larynx. In addition, I have examined 301 persons who have lived in contact with infectious pertussis patients for at least one week; these examinations were made with the cough-plate method combined with pharynx and larynx cultures. I have further examined 30 patients with pharyngeal diphtheria, 12 patients with croup, 11 patients with pseudocroup, 22 patients with scarlet fever, 18 patients with measles, 22 patients with bronchitis, 12 patients with bronchopneumonia, 19 patients with catarrhal cough, 30 patients with influenza, 10 patients with pulmonary tuberculosis, 6 patients with pharyngitis, and 10 patients with laryngitis, a total of 202 patients suffering from various diseases of the respiratory tract with the exception of whooping cough.

In this material the presence of pertussis bacilli was not demonstrated in any case except in 9 out of the 301 persons who had lived in contact with infectious pertussis patients; these 9 persons all acquired whooping cough.

The fact that whooping cough is still one of the most common diseases in children, together with the other fact that the source of infection often is quite unknown, suggests very strongly that the infection is not infrequently spread by patients in whom whooping cough is unrecognized. In fact, several investigators have demonstrated Bordet-Gengou bacilli in patients with abortive whooping cough, and others have verified such cases by means of the complement fixation test. Clinical experiences show that adults and older children often have whooping cough in an atypical form, and that the same applies to pertussis patients after prophylactic vaccination or after vaccination in the first stage of the disease.

It is difficult, however, to judge with any fair degree of certainty as to the frequency of these abortive cases of whooping cough.

I shall briefly report the series of examinations comprising eighty families in which whooping cough made its appearance. The presence of this disease was ascertained by demonstration of Bordet-Gengou bacilli in the cough-plates forwarded to the institute from members of the respective families. All the members of these families were examined once or more by means of cough-plates or by smear cultures from the pharynx and larynx. In addition, the clinical course of the various cases of whooping cough in these families was followed very closely, and attempts were made to trace the source of infection. This series of studies covers 385 persons, 202 aged under 15 years and 183 aged over 15 years. Of these, 301 have been mentioned before, in the investigations on chronic carriers of pertussis bacilli.

Seventy-six of the persons under 15 years had clinically typical whooping cough; in these cases the presence of Bordet-Gengou bacilli was demonstrated by the serum institute in the beginning of the disease. Forty children had abortive whooping cough without typical paroxysms or vomiting, but with noncharacteristic coughing that lasted about one month. The remaining eighty-six children were not attacked.

In sixteen of the forty children with abortive whooping cough, the diagnosis was established by demonstration of the Bordet-Gengou bacillus; in twenty-four, the diagnosis was strongly supported by the protracted coughing that appeared after the patient had been exposed to pertussis infection and further by the fact that these patients in all probability had transmitted the infection to other persons who then had clinically typical whooping cough.

Among the 183 persons over 15 years, 1 had clinically typical whooping cough, 4 had abortive whooping cough, and 178 were not attacked.

In all, among 202 children (up to 15 years) whooping cough occurred in 116, and in 40 of these (i. e., about 35 per cent) it took an abortive course. In 183 adults there were 5 cases of whooping cough, 4 of these being abortive.

Thus, it is reasonable to assume that abortive cases of whooping cough, often not recognized, are very frequent. As a rule, they occur in older children or adults, in persons who have had whooping cough before, or in patients who have been vaccinated against this disease.

SUMMARY

1. The results of my examinations are comparable with the hypothesis that the Bordet-Gengou bacillus is the etiologic agent of whooping cough.

2. The cough-plate method has been used for sixteen years at the State Serum Institute in Copenhagen and has proved to be of practical value. It is the best method for diagnosing the disease early.

3. An isolation period of four weeks after the onset of the typical paroxysm has in practice been sufficient for school children.

4. Healthy carries have not been found outside of families in which whooping cough exists.

5. Abortive and quite atypical cases of whooping cough are frequently found, and I believe they play an important rôle in the spread of the disease.

Clinical Notes, Suggestions and New Instruments

A CLINICAL METHOD OF VENOUS PRESSURE DETERMINATION

HAROLD F. ROBERTSON, M.D., PHILADELPHIA

Assistant Visiting Physician, Staff of Dr. William E. Robertson, Philadelphia General Hospital; Instructor in Medicine, Staff of Dr. David Riesman, University of Pennsylvania School of Medicine; Assistant Dermatologist and Syphilologist, Staff of Dr. Joseph V. Klauder, Wills Eye Hospital

In congestive heart failure, the venous pressure reading is of inestimable value. This determination offers a useful means of rating cardiovascular insufficiency. Under normal conditions the heart transports as much blood as comes to it, and there is merely a temporary rise of venous pressure. In cardiac decompensation, however, the load of the heart exceeds its physiologic response. It cannot convey into the arterial circulation the blood that comes to it from the venous circulation. Venous engorgement and stasis result, with a consequent failure of the ventricles. The increased burden on the heart produces cardiac dilatation with consequent heart failure. It has been shown experimentally that the decompensated heart needs more oxygen than the normal heart, whereas under the foregoing conditions its supply of oxygen is actually lessened. The coronary circulation is decreased, which further lowers cardiac efficiency. Venesection, in such instances, may prove a life-saving measure. Eyster¹ states: "The value of venesection in reducing the proportionately high venous blood volume, and the abnormal initial load on the right ventricle, is clearly demonstrated. Improved oxygen utilization by the cardiac muscle, increased coronary flow resulting from slower, stronger contractions [digitalis], and the lowered venous pressure offering less hindrance to the return flow from the coronary sinus are important factors in reducing the anoxemia of the heart muscle as compensation begins to be restored. Ventricular competence is regained when, by improvement in the heart muscle and by reduction of the venous engorgement by rest, venesection or other measures, the muscle begins to respond to the increased load by increased work. As the muscle becomes more efficient in its response, the venous load diminishes and cardiac output and venous pressure return to their normal ranges."

A practical means of estimating venous pressure is here described. This method originated with Gaertner² in 1903, and the author has applied it as a measure of determining the optimum time at which venesection will prove beneficial. Since phlebotomy relieves venous congestion and thereby lessens the load on the heart, and since venous pressure is a measure of venous stasis, the utilization of this method provides a means by which the clinician may be more closely guided in the management of cardiac failure.

1. Eyster, J. A. E.: *Clinical Aspects of Venous Pressure*, New York, Macmillan Company, 1929.

2. Gaertner, Gustav: *Die Messung des Drucks im rechten Vorhof*, München. med. Wchnschr. 1:2038 (Nov. 24) 1903.

METHOD

A prominent vein is selected on the dorsum of the hand. The hand is first lowered until the vein is full. It is then raised slowly with the arm fully extended until the level of the right auricle is reached whence, in the normal person, the vein is seen to go from a state of filling to one of collapse. In cardiac congestion, however, the outstretched hand must be raised considerably above this zero pressure level to a height consistent with the amount of venous pressure present. If the pressure is high, it is then necessary to raise the hand to an appreciable height above the level of the right auricle. This distance can be measured as a rough approximation of the venous pressure. When this pressure head becomes less after one or more venesections, again it furnishes a roughly measurable factor. The collapse of the vein occurs when the venous pressure falls to a level not exceeding the hydrostatic pressure. "The vein represents a manometric tube connected with the right auricle. If this is compared with the estimated level of the right auricle, one can express the venous pressure in millimeters of water."

The importance of this procedure is readily demonstrated after a venesection, at which time it is found that the venous pressure is lowered. If the heart tonus is such that recovery can take place, then the pressure remains lowered because of the lessened load and improved circulation. If it is too badly damaged and cannot respond, the venous pressure will be seen not to decrease materially. There is, thus, a prognostic value attached to this procedure as well as a method enabling one to decide when venesection is or is not indicated.

SUMMARY

The description of a method is here given for the bedside determination of venous pressure without the use of apparatus. Its clinical significance lies in the fact that it is of invaluable aid in ascertaining the advisability of either single or repeated venesections. It also is of prognostic value, since in cardiac decompensation, if the venous pressure remains lowered after venesection, the conclusion may be reached that the circulatory system has sufficient reserve left to respond to a decreased venous load.

This is not to be construed as a new observation but merely as the application of Gaertner's method to venous pressure, particularly when venesection is to be employed.

327 South Seventeenth Street.

FAULTY BLOOD GROUPING DUE TO AUTO-AGGLUTININS: AN UNUSUAL CASE

PERRY J. MANHEIMS, M.D., AND ENDRE K. BRUNNER, M.D., NEW YORK

For many years, serologists have been interested in the comparatively rare phenomenon of auto-agglutination. This has been quite clearly defined by Boxwell and Bigger¹ in the following simple sentence: "Autohemagglutination is a clumping of erythrocytes into irregular masses, visible to the naked eye, occurring in the presence of the individual's own serum, without bacterial action, at air temperature and reversible at body temperature."

Landsteiner,² Clough and Richter,³ Li Chen-Pien⁴ and other investigators have shown that the auto-agglutinins are present in the blood serum and are dependent on a lower than body temperature and fixed to the red blood cells. The auto-agglutinins can then be freed from the red cells by washing and suspending in warm saline solution, in which solution they can be demonstrated.

The case reported here is the first instance in our experience in which the phenomenon of auto-agglutination caused a faulty blood group diagnosis to be made.

A. Z., a female, was admitted to the medical service of the Lenox Hill Hospital with a hemoglobin reading of 15 per cent, as done by the Sahli method, and a red cell count of 780,000, with the accompanying blood picture of a myelogenous leukemia. An immediate blood transfusion was ordered, and blood was taken for grouping into two small test tubes, one of which contained 2 per cent sodium citrate solution for the red cell suspension, and the other tube received blood which was centrifugated for the serum to be used in cross matching. The routine slide method of grouping was used and there was marked agglutination of the patient's red blood cells, as we thought, by both 2 and 3 grouping serum. A diagnosis of AB (group 4 Jansky) was made and a professional blood donor of that group ordered. On cross matching the blood of the patient and the donor, it was found that the donor's red blood cells were agglutinated by the patient's serum and vice versa. It has occasionally happened that a donor's red cells have been agglutinated by the serum of a patient of the same group, and this has usually been demonstrated as having been due to cold or to auto-agglutinins in the patient's serum by merely mixing the patient's serum and his own red cells at room temperature.

This was done, and there was a very rapid agglutination of the patient's red blood cells by her own serum. It is known that this does not occur at body temperature, and in previous instances of this kind we have gone ahead with the transfusion with no untoward results. But the red blood cells of this patient were also incompatible with the donor's serum, which should not happen with an AB donor whose serum contains no iso-agglutinins. Furthermore, in taking blood from a patient with a very severe anemia the proportion of red blood cells to the serum is very small. Therefore, we suspected that perhaps the auto-agglutinins in the patient's serum contained in the citrated blood might have influenced the original blood grouping.

The red cell suspension was then centrifugated, the supernatant citrate serum was pipetted off, and the red cells were washed with physiologic solution of sodium chloride and then used for a regrouping. This time there was no agglutination with types 2 or 3 grouping serum, and the patient was reclassified as an O (Jansky 1). It was then concluded that the agglutination of the patient's red cells in the original grouping was caused by her own auto-agglutinins; that the citrated red cell suspension used in this grouping contained an unusually large amount of the patient's serum, owing to her extreme anemia, or that the agglutination might have been due to the auto-agglutinins that the red blood cells of the patient had absorbed from her serum at the lower than body temperature.

After we were quite convinced that the patient was an O, a donor of that group was called and on cross matching his serum with the washed red cells of the patient's, no agglutination was seen. His red cells were agglutinated by the patient's serum at room temperature, owing to her auto-agglutinins, but since this would not occur at body temperature and also since the cells of an O are not agglutinated by the serum of any group, the transfusion was given. No reaction occurred.

For the purpose of checking our results, the patient's blood was also grouped against that of two other individuals; a known O and a known AB. With the O donor's serum, the patient's washed red cells were perfectly compatible, while the tests between the donor's serum and the patient's original unwashed citrated red cells, and the patient's serum and the donor's red cells both showed marked agglutination. The cross matching with the blood of the second AB individual and patient again showed the patient's unwashed red cells and the donor's red cells to be agglutinated by each other's serum, while there was no agglutination of the washed red cells of the patient by the second donor's serum.

Aside from the purely serologic interest that this case presents, it brings out two practical points as regards blood transfusion: Merely grouping a patient and procuring a donor of that group is not giving the patient sufficient protection against being transfused with incompatible blood. Every donor and patient should be cross-matched. Furthermore, in any instance in which auto-agglutinins are demonstrable in the blood of the patient, a regrouping should be done, washed red blood cells being used.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
PAUL NICHOLAS LEECH, Secretary.

INTRAVENOUS USE OF BARBITAL COMPOUNDS (II)

In 1931 the Council adopted and published a report giving the status and limitations of the use of barbitol compounds intravenously for anesthesia (*THE JOURNAL*, Dec. 19, 1931, p. 1886). The Council at that time decided on definite limitations for the intravenous use of these compounds for induction of anesthesia and sponsored the following statement: "Their intravenous use should be limited for the present to conditions in which oral administration is not feasible either because the patient is unconscious, as in cerebral hemorrhage, eclampsia, or status epilepticus, or because he resists, as in delirium, or because a very prompt action is imperative, as in convulsion from local anesthesia."

In the consideration of sodium amytal and the brands of pentobarbital sodium, the Council recognized that these drugs might be administered intravenously in the conditions mentioned in its report and laid down the following stipulation with regard to propaganda for their intravenous use: "The acceptance is subject to the continuance of the agreement under which the products are to be sold and distributed, namely, that they will not be sold for intravenous use in the open market but may be sold to hospitals and institutions for investigation purposes; and that the intravenous products will not be advertised nor propaganda made for the intravenous use of soluble barbitol compounds for the induction of anesthesia. On the other hand, the Council recognizes that barbitol derivatives can be administered intravenously in conditions in which oral administration is not feasible either because the patient is unconscious, as in cerebral hemorrhage, eclampsia or status epilepticus, or because he resists, as in delirium, or because a very prompt action is imperative, as in convulsions from local anesthetics; and has decided that such use may be mentioned in the advertising for these products.

In the recent consideration of Pernoston, a barbituric acid derivative marketed only in injectable form, the question was raised as to whether or not in the light of accumulated experience it was desirable to relax the limitations which the Council had placed on the intravenous use of barbitol compounds. It was determined to send a questionnaire to a selected list of surgeons, anesthesiologists and others asking whether they considered that the time had arrived when the Council should agree to the advertising of preparations of soluble barbiturates for intravenous injection for induction of anesthesia.

The following replies to the questionnaire were received and are published (in alphabetical order) with the consent of the respective consultants:

Letter from Dr. Willard Bartlett, St. Louis:

"In our opinion the situation in regard to the intravenous use of the barbituric acid compounds has not changed since the publication of the report of the Council in 1931. Both clinical and experimental work, the literature of which we have followed with the closest interest, confirms the important facts in the matter as follows:

"1. The desirable effects of the drugs are obtained by oral or rectal administration.

"2. Oral and rectal administration of divided doses make it possible to test every individual for idiosyncrasy.

"3. There is a risk inseparable from the intravenous administration which, although that risk be remote, does not, in view of the foregoing facts, justify intravenous administration except in such an emergency as the convulsions of tetanus.

"4. It is our own feeling that the position of a doctor who, in the absence of a gross emergency, gave one of the barbituric acid compounds intravenously and had a fatal accident occur would be difficult to defend in court in view of these facts and the general opinion of nonmedical authorities qualified to hold an opinion on the subject.

"5. The clinicians who formerly wrote glowingly of the advantages of intravenous administration have not only modified their tone on the whole but have turned to oral and rectal administration as routine.

"In conclusion we believe it would be a mistake to allow the broadcasting of advertisements which would in any way encourage men not thoroughly familiar with these drugs to use them intravenously."

Letter from Dr. W. J. Bleckwinn, Madison, Wis. (in part):

"Concerning the question which was raised in your letter of the intravenous use of barbiturates in the field of anesthesia, I would say that I have no opinion other than that expressed in an article read before the Wisconsin State Medical Society at Milwaukee. I am in accord that the barbiturates are not analgesic and therefore I do not believe that, with the dosage necessary to produce the degree of unconsciousness for surgical work muscular relaxation and analgesia will occur.

"I am not interested in surgical anesthesia and am therefore unable to express an opinion of any value concerning the use of this series of drugs in surgical anesthesia but I am firmly of the opinion that they are invaluable in controlling convulsions from strychnine, tetanus, status epilepticus, eclampsia, to counteract overdoses of cocaine, the wild deliriums due to either infectious disease or intoxication, in the prevention of the acute exhausted states associated with the deliria seen by the general practitioner before such patients are sent to the proper institution and, of course from my own viewpoint the most important of all, the application of barbiturate therapy in the field of psychiatry. I wish to emphasize one fact, in the light of our experience of four years, that no oral administration of these drugs can compare with the intravenous medication in the above mentioned conditions and again, for the sake of emphasis, the importance of the proper technic of administration in avoiding the untoward reactions reported at your Council meeting and experienced by all of us before this proper technic was followed."

Letter from Dr. Hugh Cabot, Rochester, Minn. (in part):

"Please pardon my delay in answering your letter of March second asking my opinion as to the position taken by the Council on Pharmacy and Chemistry in regard to whether or not the time has arrived when the Council should permit the advertising of preparations of soluble barbiturates for intravenous injection for induction of anesthesia." I have delayed answering it in order to be quite sure that I might express the opinion which I really held.

"I think the time which has elapsed since the previous report of the Council in December, 1931, has added importantly to our knowledge of the fields in which these preparations are useful. At that time there was considerable use of these preparations for or in connection with general anesthesia for surgical operations. Its use in this field has, I think, very much diminished, and I doubt whether as time goes on it will survive for this purpose. On the other hand, during the same period the value of the drug used intravenously for other purposes, chiefly in tetanus, eclampsia and strychnine poisoning, has been pretty satisfactorily demonstrated.

"It seems to me that it is now very desirable that preparations of the barbiturates for intravenous use should be on the market and readily obtainable. When they are needed, they are needed promptly, and I think physicians and hospitals can hardly be expected to keep them on hand unless they are obtainable through normal channels. I believe, therefore, that the previous ruling of the Council might properly be modified in this respect since I am firmly of the opinion that for the purposes above mentioned no method of administration other than intravenous can be relied upon to produce the desired effects."

Letter from Dr. Edward D. Churchill, Massachusetts General Hospital (in part):

"In direct answer to your question it is my opinion that the Council should not permit the advertising of preparations of soluble barbiturates for intravenous anesthesia. In very special cases this method may be employed but only by individuals well conversant with the pharmacological action and dangers of these preparations. I feel that the margin between safety and danger with anesthetic doses of barbituric acid compounds is too small and the liability for variations in individual susceptibility too great to recommend this form of anesthesia to the profession at large."

Letter from Dr. George W. Crile, Cleveland:

"In response to your letter of February 20, I should say that there is a sound principle which contraindicates the use of intravenous anesthesia in any form whatsoever. The reason for this is obvious. The anesthetic is irrecoverable and should there be an overdose it would be fatal. Moreover, these anesthetics anesthetize all protoplasm, not the brain only, and hence they should be used only in cases in which there is a good factor of safety, that is to say, intravenous anesthesia should never be used in cases in which the patients are depressed by shock, hemorrhage, disease, infections, etc."

Letter from Dr. Elliott C. Cutler, Peter Bent Brigham Hospital, Boston:

"I am wholeheartedly opposed to such action on the grounds (1) that any anesthetic which has to be given intravenously and for which there is not a specific chemical antidote which can stop the anesthetic at once is always a danger to the patient; and (2) that there are other anesthetics much more suitable and equally efficacious in all conditions.

"I should hate to see the Council popularize this drug, though I cannot say from personal experience that it has grave dangers."

Letter from Dr. Charles Gordon Heyd, New York:

"I do not believe the time has arrived when the Council should permit the advertising of preparations of soluble barbiturates for intravenous injection for induction of anesthesia.

"Intravenous anesthesia by the barbiturates makes the induction of anesthesia a matter of trifling technical procedure. It allows the induction of this type of anesthesia in a physician's office and in many cases the anesthesia will tend itself to an extension of office surgery or criminal abortions. It is not without danger and its administration, if possible, for anesthesia purposes should be confined to hospital practice.

"I am enclosing herewith a reprint of an article bearing on the subject (*Am. J. Surg.*, July, 1930, pp. 29-35).

"I see no reason why it cannot be employed in hospital practice where the safeguards are usually adequate to protect the public against the possible implications mentioned above."

Letter from Dr. Carl H. Lenhart, Lakeside Hospital, Cleveland:

"I have had some bad experiences with intravenous use of barbitol preparations, and I am no longer interested in them. Naturally I am prejudiced against forcing its use upon the medical profession by advertising methods."

Letter from Dr. John S. Lundy, Mayo Clinic, Rochester, Minn. (in part):

"I think that the soluble barbiturates for intravenous injection should be made available to every physician for emergency purposes and that the commercial houses should be encouraged to make them available. However, so far as advertising is concerned, the matter should so read that it will be understood that the drug is a definite antispasmodic and is an anesthetic and that it may be used essentially for either or both purposes in an emergency but that it is not intended for routine use."

Letter from Dr. E. I. McKesson, Toledo, Ohio (in part):

"While it is admitted that the injudicious and indiscriminate use of these drugs is capable of harm, we feel that the decision as to when they should be employed might better be made by the physician using them. It does not seem fair that the profession as a whole should be denied free use of drugs simply because bad results may follow their ignorant or careless administration."

"It is our opinion that the general advertisement and sale of soluble barbiturates for intravenous use should be permitted."

Letter from Dr. I. S. Ravdin, University of Pennsylvania School of Medicine:

"I believe I am correct when I state we were the first to use sodium amytal for basal anesthesia in man. From the time we first began until the present time we have felt that the intravenous use of the barbiturates was dangerous. As our experience with the barbiturates has increased we have felt that their administration by mouth or by rectum, preliminary to narcosis with other agents, is often advantageous. We have, however, become more and more convinced that they should never be used beyond the point of basal anesthesia, and even then, we believe, one is not justified in using the barbiturates for basal anesthesia routinely."

"There seems to be no reason why the barbiturates should be given intravenously except on the rarest of occasions, since the oral and rectal administration will give satisfactory results in the majority of instances. In the delirious or psychopathic patient the intravenous use of the barbiturates is no doubt indicated; but looking back over an experience of six years I believe the indications for the intravenous use are limited to this group."

"The portion of the Council's statement beginning with 'Their intravenous use should be limited' seems to me to cover the indications for the intravenous use of the barbiturates. I do not believe it is safe to go beyond this statement."

Letter from Dr. L. F. Sise, Lahey Clinic, Boston:

"I believe that manufacturers should be allowed to advertise such use, but for basal anesthesia or narcosis only, and not for complete anesthesia. The reasons for this opinion are as follows:

"1. There is a field of usefulness for the intravenous administration of these drugs in conjunction with other agents. Our experience in the past in this field has been very satisfactory. The field is quite narrow and at the present time we are not thus using barbiturates, partly because of the narrowness of the field; partly because tribrom-ethanol has with us replaced this use, and partly because the oral administration of barbiturates is more convenient and practical in a busy clinic."

"2. The use of barbiturates for complete anesthesia is not advisable."

"3. Because there are undesirable effects and dangers connected with the intravenous use of the soluble barbiturates is no reason why they should not be thus used. A large proportion of the most useful procedures in medicine and surgery have undesirable effects and dangers connected with them if they are not properly used."

"4. It is highly desirable that these products be on the market and conveniently on hand for intravenous use in certain emergency conditions. I feel that the wider field of advertising of these products would be an aid in keeping them readily available."

Letter from Dr. Arthur L. Tatum, University of Wisconsin:

"Intravenous injections of short acting barbiturates are occasionally justified:

"(a) For preanesthetic depression (not complete surgical anesthesia) in special cases where immediate sedation or hypnosis is required or desirable. In trained hands, intravenous injections can be better quantitated than when the barbiturate is given per os, where variations of absorption occur. However, the intravenous method of administration should not become routine because of possible abuse. By comparison, however, hypodermics of morphine and scopolamine are common and accepted as justified."

"(b) For antidoting of convulsive poisoning, quick action is required; hence, intravenous administration is fully justified. Certain cases of dementias are included in this group."

"For ordinary hypnotic uses, the barbituric acid is essentially identical to the sodium salt, since the stomach is normally acid which precipitates the barbituric acid in the stomach."

"We are adamant in insisting on individualization of preanesthetics as well as anesthetics according to the requirements of each individual

case. Routinization in use as preanesthetic depressants is strongly condemned."

"If barbiturates are chosen for preanesthetic depression, the operator should base his choice on whether or not a short, medium or long period of hypnotic depression is desired."

"Finally, people will give intravenous injections of barbiturates as preanesthetic depressants regardless of advertising, so if caution is insisted on, i. e., limiting recommendation only in selected and special instances, perhaps this positive limited recommendation would do more good than not to have so stated it."

Letter from Dr. Soma Weiss, Boston City Hospital (in part):

"As far as the practice of surgeons is concerned in this hospital, and other hospitals with which I am familiar, it is my impression that this problem is still entirely in a rather chaotic and experimental stage. Following the early and rather enthusiastic reports concerning amytal particularly, various barbituric acid derivatives have been used by surgeons in relatively high doses. Although large doses are still used by various surgeons, especially those in smaller communities, it is my impression that gradually through sad experiences surgeons are refraining from using barbituric acid derivatives in relatively large doses."

"I believe that the report of the Council, published in 1931, on the Intravenous Use of Barbitol Compounds is still up to date. I may say that in this article the rôle of the relation between the state of the central nervous system and the dosage of the barbituric acid derivatives is somewhat underestimated. The greatest danger in the intravenous use of barbituric acid derivatives in surgery is due to the fact that, as a result of varying degrees of surgical trauma, loss of blood and other complications, the dose of barbituric acid derivatives which in one patient would not be toxic may become toxic in another individual. I am certain from observing patients, as well as from animal experiments, that in the presence of depressed central nervous system, particularly in shock, smaller doses will prove to be fatal. It is also very probable, although I have not had experience in this, that the detoxication and elimination of the barbituric acid derivatives in the presence of shock will be considerably lowered. As one can never tell in surgery when such emergency will arise, the recommendation of the routine use of intravenous administration of any substance in amounts that produce hypnosis and of any substance which has a relatively long persistent action cannot be advocated."

"There may be, on the other hand, certain special indications when a relatively large dose of barbituric acid derivatives can be given intravenously. Such indications may be, if for certain reasons volatile anesthetics are contraindicated. The upshot of all these considerations is that barbituric acid derivatives in the induction of anesthesia should be used only as adjuvants, similar to the use of morphine, scopolamine, etc. As such, it should be pointed out that they are absorbed well by mouth, and the effect of oral and intravenous administration is quite similar. If, therefore, for some reason, oral administration of such relatively small doses is not feasible, intravenous injection is permissible."

"As to the size of the dosage in such cooperative use of the barbituric acid derivatives, they should be relatively low and should be somewhere between 10 and 20 per cent of the fatal dose. There is some indication, and opinions to this effect are frequently expressed, that these relatively small doses reduce the amount of volatile anesthetics needed."

"In looking over my publication on this problem in the *American Journal of the Medical Sciences*, 1929, volume 178, page 390, I believe that on the whole I still maintain the same opinion as to the indications and danger of the barbituric acid derivatives as expressed there."

"If there is any additional information that you would like on this matter, please do not hesitate to call on me."

The Council has given careful consideration to the replies to the questionnaire, and it believes that the evidence overwhelmingly sustains its previous conclusion concerning the limitations for the use of the soluble barbiturates in the induction of anesthesia. The Council therefore has reaffirmed its previous decision with reference to the advertising of these substances.

§ DOCTOR'S PRESCRIPTION POWDER NOT ACCEPTABLE FOR N. N. R.

"§ Doctor's Prescription Powder" is marketed by the Dermic Laboratories, New York. In the information submitted by the firm for the Council's consideration the product was stated to have the following composition:

1¼ lbs. Salicylic Acid U. S. P.
3½ lbs. Boric Acid U. S. P.
1¼ lbs. Zinc Stearate U. S. P.
2½ lbs. Ammonium Alum U. S. P.
2 lbs. Zinc Oxide U. S. P.
175 lbs. Talcum Powder.

No statement of composition appears on the trade package, on which the preparation is stated to be "Scientifically prepared for the relief of athlete's foot . . . Bromidrosis (Excessive Perspiration) . . . Eczemas." The product is also stated on the label to be "the formula of an experienced and well known Physician." Under "Directions" it is stated, among other things, that the product is "Ideal for all affections caused by heat," "Sanitary Napkins. To deodorize use freely."

The statement of composition shows that the preparation is unnecessarily complex and the name gives no information

as to the ingredients. There is no evidence that such a complex mixture is more effective than a simpler mixture for the relief of some of the conditions mentioned on the trade package. In particular, there is no evidence that this or any other deodorant will deodorize sanitary napkins as claimed on the trade package. The Federal Trade Commission recently issued the following ruling on consent of the Sanitary Napkin Industry:

"The use of the term 'deodorized,' or similar terms or expressions, in the advertising or sale or offering for sale of sanitary napkins in a manner calculated to mislead or deceive the trade and purchasing public into believing that the said sanitary napkins contain a deodorant or possess deodorant properties, when such is not the case, is an unfair trade practice."

The Council declared "R Doctor's Prescription Powder" unacceptable for New and Nonofficial Remedies because it is an unnecessarily complex mixture marketed under a noninforming name with no statement of composition and with unwarranted and exaggerated therapeutic claims.

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT.

PAUL NICHOLAS LEECH, Secretary.

ALPHA-DINITROPHENOL

Elsewhere in this issue appears an article by Cutting, Mehrtens and Tainter on dinitrophenol. As this compound is relatively new both to pharmacology and to clinical medicine and is not described in standard works on materia medica, the editor of THE JOURNAL requested that it be considered by the Council. Accordingly, the Council has adopted the following for publication as a preliminary report:

Alpha-dinitrophenol (1:2:4) OH

is a compound known in industry chiefly as an intermediate in the manufacture of explosives. It came into prominence in France during the World War, when it was extensively employed in the production of munitions. Numerous cases of poisoning occurred in factory workers handling the material; not a few of those exposed developed headache, dizziness, vomiting, high fever and other alarming symptoms, followed in some instances by sudden death. These accidents grew so numerous that it was proposed at one time to abandon the manufacture of this compound despite the then great demand for it. Fortunately, hygienic measures instituted after the source of the intoxications had been traced completely prevented further casualties.

In the extensive pharmacologic scrutiny to which dinitrophenol 1:2:4 was subsequently subjected, several highly interesting properties came to light. In particular this compound was found to produce marked hyperthermia in animals; this led to death if the dosage was large enough.

Cutting, Mehrtens and Tainter and their co-workers have found, as reported in their paper, that the administration of dinitrophenol in proper dosage may result in acceleration of cellular metabolism, both in animals and in man, without apparent evidence of deleterious effect. They therefore propose the clinical use of this compound in individuals in whom acceleration of the metabolic rate may be of value. Dinitrophenol appears, in some conditions, to have advantages over thyroxine for this purpose.

The authors realize, of course, that their very extensive investigations have not yet ruled out beyond a reasonable margin of doubt the possibility of remote toxic effects in the clinical use of dinitrophenol, somewhat as liver atrophy has occurred after cinchophen. Their conclusion, in which the Council concurs, is therefore reproduced herewith: "There are limitations to and possible dangers from the use of the drug clinically. It should be used only under strictly controlled conditions."

Alpha-dinitrophenol is at present available on the market for chemical use only and is not sold as a drug. The Council has therefore deferred further consideration of this preparation until more evidence is adduced for its therapeutic usefulness.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
RAYMOND HERTWIG, Secretary.

NOT ACCEPTABLE

VI-TONE (MALT CHOCOLATE FLAVOR)

The Vi-Tone Company, Hamilton, Canada, submitted to the Committee on Foods a chocolate flavored powder "Vi-Tone (Malt Chocolate Flavor)" containing malt extract, sucrose, glucose, coconut oil, skim milk, soya bean, calcium phosphate and salt. It is intended for the preparation of a beverage with milk or water.

Discussion of Label.—The label prominently defines the product as "A tonic food beverage—an extraction of malt and milk—rich in proteins and vitamins of the soya bean" and states that "Vi-Tone should never be boiled as the diastase, vitamins and other digestive principles are destroyed in this manner." This food is no more a tonic than are other foods. The designation "tonic food" is deceptive because it implies special medicinal or therapeutic values.

The description "an extraction of malt and milk—rich in proteins . . . of the soya bean" is an incomplete statement of ingredients. Descriptive statements accompanying fanciful trade names such as "Vi-Tone" should be complete and include all ingredients arranged in the order of their descending proportions by weight in the product.

The claim "rich in vitamins of the soya bean" connotes that soya bean and the product are rich in all the vitamins; soya bean is a poor source of vitamins A and C. Vitamin claims should specify the vitamins referred to.

"Rich in proteins of the soya bean" implies that soya bean is a major ingredient of the product, whereas it is present in a rather small proportion.

The statement regarding the destruction by boiling of "diastase, vitamins and other digestive principles" leads the reader to believe that the product is valuable for its "digestive principles." The product may be diastatically active because of the malt extract ingredient, but any starch digestive effect it may have on the starch of other ingested foods is unimportant. The starch digestive powers of a small amount of saliva swallowed with foods is more effective.

Discussion of Advertising.—An advertising leaflet entitled "VI-TONE TO THE HEALTH OF THE NATION" contains numerous exaggerated and unwarranted statements:

"VI-TONE MAINTAINS YOUTH, VIGOR AND ENERGY." "VI-TONE VITAMINES—THE FIRST ESSENTIALS OF LIFE AND HEALTH." "The three greatest sources of digestible vitamins are the soya bean, malt and milk, and these are combined to make Vi-Tone . . . —it supplies that vital energy that is indicated by the name Vi-Tone. The malt in Vi-Tone also contains diastase, a vegetable digestant, which converts the free starch in other foods, such as potatoes and white bread, into a form which makes it easily assimilated by the system. Starch cannot digest in the gastric juices, which are acid, without diastase. Vi-Tone is not only itself easily digested, but it thus increases the value of all other foods. Men and women with saw-toothed nerves need Vi-Tone. The fagged feeling that follows a tense day at the office or in social duties does not come from tired muscles; but from nerves that have been drained of their vitality. The nerves are fed and revived by Vi-Tone. The student whose brain refuses to function further, because it has reached the limit of endurance, does not crave heavy food because he does not require it. Vi-Tone fills his need. The aged and infirm find renewed life and vigor in Vi-Tone. It stimulates the appetite, aids digestion and improves the general health. Children are full of the spirit of life and fun when their bodies are abundantly supplied with vitamins. Their subconscious minds know what they need and lead them instinctively to Vi-Tone. . . . Vi-Tone may be used as a reducer when taken hot or cold for breakfast or lunch instead of heavy foods. It contains the required nourishment. Vi-Tone, for those who suffer from malnutrition, or are anaemic, thin and weak, will build up the system with rich red blood and firm flesh. . . . It improves digestion and enables the system to assimilate the full nourishment from other foods, thus correcting malnutrition. As a natural consequence, it prevents constipation. . . . Physicians know the value of Vi-Tone and gladly recommend it. Ask your own doctor. The scientific combination of the soya bean, malt extract and milk all so rich in protein and vitamin content goes to make the delicious easily digestible chocolate flavored Vi-Tone, supplying that vital energy indicated by the name. Radiographers use Vi-Tone in connection with gastro-intestinal examination making a most delicious drink for Barium suspension and as a diet in Mucus Colitis and kindred ailment. Physicians strongly recommend Vi-Tone."

This advertising represents a crude attempt to transform Vi-Tone into a "patent medicine food." It is even claimed that this high caloric food "may be used as a reducer"; although it provides little indigestible residue it is stated that "it prevents constipation." All the prevalent misleading claims adopted for so-called health foods, with hardly an exception, are brought into service for Vi-Tone. For giving final authoritative support to the alleged medicinal claims, it is stated that "physicians strongly recommend it."

Such advertising degrades the sale of foods to the level of deception used in promoting nostrums and is a cruel exploitation of the public.

The manufacturer was informed of the Committee's report but has not demonstrated that any steps have been taken to correct the label and advertising in accordance with the Committee's recommendations. Vi-Tone therefore will not be listed among the Committee's accepted foods.

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

BUY JIMINY (A PEANUT BAR)

Manufacturer.—The Curtiss Candy Company, Chicago.

Description.—A bar containing peanuts, sucrose, corn syrup, coconut butter and salt.

Manufacture.—The sugar and glucose are cooked in open kettles until a temperature of 118 C. is obtained; a portion of the peanuts is added and the mass is cooked until the peanuts are roasted and a definite temperature is reached. The coconut butter, salt and the remainder of the peanuts are added; the mix is heated until a definite temperature is attained; it is uniformly spread on a steel belt and automatically cut into bars, which are refrigerated and wrapped.

Analysis (submitted by manufacturer).—

| | per cent |
|---|----------|
| Moisture | 1.5 |
| Ash | 1.9 |
| Fat (acid hydrolysis method)..... | 33.0 |
| Protein (N X 6.25)..... | 18.4 |

| Carbohydrates other than crude fiber (by difference)..... | 44.0 |

Calories.—5.5 per gram; 156 per ounce.

WHITE HOUSE RICE FLOUR

Manufacturer.—Standard Rice Company, Inc., Houston, Texas.

Description.—Scoured rice flour.

Manufacture.—Scoured rice is pulverized between corrugated rolls and sifted over silk cloth; the flour passing through the silk is automatically packed in wax-paper wrapped cartons.

Analysis (submitted by manufacturer).—

| | per cent |
|---|----------|
| Moisture | 9.3 |

PURE GOLD BREAD

Manufacturer.—The Kilpatrick Baking Company, Denver.

Description.—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817); prepared from patent flour, water, sweetened condensed skim milk, sugar, lard, salt, dry whole milk, yeast, diastatic malt syrup, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

LUCKY GLUTEN FLOUR

Manufacturer.—Federal Mill, Inc., Lockport, N. Y.

Description.—Wheat gluten flour containing not more than 44 per cent of starch.

Manufacture.—The gluten flour is prepared by admixing definite proportions of ground gluten with a "standard patent" flour. The ground gluten is manufactured from wheat flour by washing starch out of a wheat dough with water in a special machine. The starch flows away with the water, whereas the gluten with a small amount of starch remains behind as a gummy mass which is dried in "vacuum" driers and milled to a flour.

Analysis (submitted by manufacturer).—

| Crude fiber | 1.1 |
| Carbohydrates other than crude fiber (by difference)..... | 45.1 |

Calories.—3.7 per gram; 105 per ounce.

Claims of Manufacturer.—Especially manufactured for recipe preparations for special diets. Fulfills United States Department of Agriculture definition and standard for gluten flour.

NESTLÉ'S, IDEAL, LA LECHERA, MILKMAID, ALPINE BRANDS UNSWEETENED EVAPORATED MILK

Manufacturer.—Nestlé's Milk Products, Inc., New York.

Description.—Unsweetened, sterilized evaporated milk. The same as Alpine, Lion and Everyday Brands Sterilized, Unsweetened Evaporated Milk (THE JOURNAL, Jan. 23, 1932, p. 319).

SCHAIBLE'S LONG BEST-YET BREAD

Manufacturer.—Schaible's Bakery, Inc., Easton, Pa.

Description.—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817); prepared from patent flour, water, sucrose, sweetened condensed skimmed milk, lard, dry skim milk, salt, malt extract, calcium acid phosphate, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

MEADOWMERE BRAND UNSWEETENED EVAPORATED MILK

Packer.—The Page Milk Company, Merrill, Wis.

Distributor.—Wm. Steinmeyer Company, Wholesale Grocers, Importers and Coffee Roasters, Est. 1864, Milwaukee.

Description.—Unsweetened evaporated milk; the same as Page Evaporated Milk, Sterilized Unsweetened (THE JOURNAL, May 30, 1931, p. 1872).

MARTINELLI'S GOLD MEDAL PURE CHAMPAGNE TYPE SPARKLING APPLE CIDER (CARBONATED)

Manufacturer.—S. Martinelli and Company, Watsonville, Calif.

Description.—Carbonated pasteurized sweet apple juice.

Manufacture.—The cider as described for Martinelli's Gold Medal Sweet Pure Apple Cider (THE JOURNAL, June 24, 1933, p. 2010) is carbonated by being pumped through a carbonator consisting of a silver lined dome filled with glass balls, over which the cider is sprayed and percolates to the bottom of the dome under a pressure of 30 pounds of carbon dioxide. From the carbonator the juice is forced by gas pressure to a high pressure filling machine, where the bottles are filled and capped under pressure. The bottled juice is pasteurized for thirty minutes at 68 C.

Analysis, Calories, Vitamins and Claims of Manufacturer.—See Martinelli's Gold Medal Sweet Pure Apple Cider (THE JOURNAL, June 24, 1933, p. 2010).

COPPER IN THE DAILY DIET

Copper occurs frequently in the various foods that enter into the human diet. The investigation of its occurrence in such materials began more than a century ago.¹ The accurate estimation of traces of copper in organic matter has offered considerable difficulty until comparatively recent times. Most persons in the past have viewed the element in food materials as a chance contaminant, the presence of which might readily become of toxicologic moment. Of late the subject has presented great interest, since the study of various forms of anemia has led to general application of the observation by Bunge in 1889 that men and mice could be made anemic by a diet of cow's milk exclusively; and of the discovery by Hart, Steenbock, Waddell and Elvehjem that a prompt regeneration of hemoglobin could be obtained in milk-fed anemic rats by administration of small amounts of inorganic copper. Newell and McCollum² of the Johns Hopkins University do not hesitate to class copper as an essential of the diet, and this conclusion is shared by many investigators who have been engaged in researches on blood regeneration.

Several years ago, Flinn and Inouye³ of Columbia University remarked that copper is so universally distributed throughout the plant and animal kingdoms as to raise the question whether it may not play some important part in the metabolic reactions of the organism. Certainly its presence in plants and animals alike cannot be explained simply by its adventitious occurrence in the soil. There is increasing evidence that, up to a certain point, copper may be beneficial to both animals and plants, but that, in excess of this quantity, ill effects sometimes, but not always, ensue. As Rose points out, the constant occurrence of copper in association with iron in the blood and tissues of men and animals, and the striking fact of its high concentration

in the liver of the new-born would of themselves justify inquiry into its physiologic significance. There have been hasty attempts to introduce the use of copper widely into human therapy of disorders of the blood, notably all types of anemia, even before the facts are well established. Granted that there may be occasional shortage of iron in the intake of man, is this necessarily true of copper? The quantity actually needed, judged by all the recent studies of nutritional anemias in animals, probably does not exceed one-tenth that of iron.

According to Flinn and Inouye, only a small fraction of ingested copper is eliminated promptly in the urine. Therefore the study of the latter excretion in man is not without interest at this time. At the Montreal General Hospital, Rabinowitch⁴ has carefully examined the urine of fifty persons selected at random except that histories were carefully taken in order to exclude cases in which there was any suggestion of undue exposure to copper through treatment or occupation. From the analytic results, copper appears to be a constant constituent of urine of normal persons. The amounts found ranged between minute traces and 0.4 mg. per liter and between traces and 0.7 mg. for twenty-four hours. In two copper "balance" experiments in which the subjects were fed copper, the amounts were appreciably larger. Obviously, people consume quite unwittingly, day by day, far larger quantities of copper than the data presented indicate. Probably there is more actual danger at present of excessive intake than of deficiency in the human dietary.⁵ At any rate the hasty inclusion of copper in present-day therapeutic programs may be ill advised. Intensive study of the problem for man is imperative.

SOME PROBLEMS OF THERAPEUTIC RESEARCH

The rapid progress that clinical medicine has experienced in recent years has been accelerated by the labors of scores of scientific laboratories. Sir F. G. Hopkins, distinguished president of the Royal Society of London, once remarked¹ that experience at the bedside and the habit of close observation are essential for the making of a successful physician. These and these alone can qualify him for the application of knowledge to the relief of human suffering; but history shows that knowledge itself grew slowly when bedside observations were its chief source. This is, perhaps, only another way of saying that the physician on whom the task of medical leadership falls needs certain types of cooperation outside the clinic to enable him to attain his highest aims most effectively.

It has been said that in the wild-goose chase for remedies in the past the result was generally negative and the physician had almost invariably to resign himself to do what he could through merely alleviating by the simplest means the most distressing symptoms of his patient. Even purely palliative or symptomatic treatment is not devoid of virtues in an age of ignorance of underlying causes or inability to avert them. There is, however, considerable danger that a widespread attitude of so-called therapeutic nihilism among physicians may delay the development of rational therapy. There have, indeed, been vigorous reforms in drug treatment in recent years. Lee² has remarked that physicians no longer administer the old mixtures of innumerable drugs, given with the comprehensive hope that some one component would hit the mark, and hence called shotgun prescriptions. Large quantities of individual drugs also are avoided, and the endeavor is made to reach only the specific functions that are disordered.

The complaint is not infrequently heard that real experimental therapeutics has often been hampered rather than helped by the selfishness and greed of commercial interests. The experience of the Council on Pharmacy and Chemistry of the American Medical Association over a quarter of a century could be drawn on to support some of these criticisms. The great development of university laboratories and endowed research institutes has therefore been looked on as the saving feature in a distressing outlook. Sir Henry H. Dale,³ the director of the National Institute for Medical Research in London, has pointed out in an inspiring address that investigation in that group of sciences which contribute to medicine entails certain special obligations. The practitioners of medicine are bound, by a tradition of long and honorable history, to place any new knowledge gained in the practice of their art freely at the disposal of their professional brethren, without any concealment or any attempt to restrict its use for private advantage. This tradition has no connection with any formal code of professional etiquette governing medical practice. Its basis is a recognition of an essential condition for the advance of medical science; and in recent years, as such advances have come in increasing measure from the research laboratories, the workers in these laboratories, whether medically qualified or not, have in many instances shown themselves eager to embrace this great medical tradition and to accept this freedom of the great medical brotherhood.

Here is an ideal that should not be abandoned. Dale further noted, however, that even laboratories supported by industrial enterprise can be, and not infrequently are, inspired genuinely by the ideals of the

advancement of medical science and of service to suffering humanity.

The investigator in the medical sciences isolated in a detached laboratory not infrequently finds real advantage in the cooperation of the specially equipped laboratories of industrial organizations where programs can be prosecuted on a large scale or with unique facilities. The laboratories of the pharmaceutical industries are often helpless without the cooperation of clinical experts. Dale is inclined to doubt whether in the field of medical science the ideal relationship has yet been everywhere established, between research in the universities and the hospitals, on the one hand, and that associated with the pharmaceutical industry on the other. The finding and acceptance of a proper relationship, however, is vital, he says, to the progress of the two alike, and to their union in an ordered advance, along the common front of medical science and its applications.

DINITROPHENOL, A METABOLIC STIMULANT

Elsewhere in this issue appears a report by Cutting, Mehrtens and Tainter of Stanford University relative to the actions and uses of dinitrophenol (1:2:4), a preparation with the apparently remarkable power of stimulating metabolism enormously, producing pyrexia, and without such deleterious symptoms as would result from equivalent doses of thyroid gland. In this issue appears also a preliminary report by the Council on Pharmacy and Chemistry concerning this substance. Some years ago Joslin remarked that it was extremely fortunate that insulin is not effective by mouth, since otherwise numerous fatal accidents might follow its use. A drug with the potency and effects of dinitrophenol is a two-edged sword with appalling possibilities for harm as well as for good.

As a result of their investigations of the product, the investigators suggest as possible uses its application in myxedema to control the symptoms that result from insufficient metabolism in that condition. They find it especially valuable in obesity, although, as has been shown in several articles recently published in *THE JOURNAL*, it is possible to obtain the maximal weight loss by dietetic bookkeeping, controlling the food intake alone. On the other hand, it has apparently been possible with dinitrophenol to reduce weight without attempting any dietary restrictions.

Because of its action in producing pyrexia, it offers opportunity for study in relationship to fever treatment of various conditions. Thus the authors mention the possibility of raising the dosage in animals to such an extent that metabolism is increased fourfold and the animal produces heat so fast that it may be killed by the resulting fever.

Obviously the use of the preparation is too new to hazard final judgment as to its value in practical medicine. Apparently it has not been determined whether

3. Dale, H. H.: *Academic and Industrial Research in the Field of Therapeutics*, *Science* 77: 521 (June 2) 1933.

or not there are cumulative effects from small doses repeated over long periods. With a drug of this potency, experiments on toxicity covering several years would not be too much to demand. The experience with cinchophen is still ripe in the minds of many clinicians. The possibility of hepatitis and even cirrhosis following the use of a drug with such remarkable powers in relationship to metabolism must be thoroughly investigated. Certainly for the present, at least, such investigations should be largely limited to controlled studies in hospitals by physicians competent in evaluating the effects of the drug, and with laboratory facilities capable of accurately determining blood, body tissue and other changes.

Current Comment

THE OAKLEY EXPERIMENT ON MOTTLED ENAMEL

In numerous American communities, the condition of the teeth known as mottled enamel exists among the residents as a local phenomenon, apparently resulting from a peculiarity of the water supply. Dean,¹ of the National Institute of Health of the United States Public Health Service, has found ninety-seven localities which have been referred to in the literature as areas where mottled enamel is demonstrable or confirmed by a survey of the locality. Recent investigators have placed the cause of this defect of the enamel of the teeth solely on the content of fluorine in the water supply. The interesting experience of the city of Oakley, an agricultural community in Idaho, points in that direction; indeed, according to McKay,² who made the survey, it adds the final proof. In the early twenties, Oakley residents became conscious that their children's teeth presented a disfiguring appearance. They saw that this condition did not exist in children who lived just outside the town but who came into town daily to school. About ten years earlier, Oakley began to use water from a spring in the hills, and six or seven years later this defect of the teeth first appeared. In 1925, McKay and Smith examined the school children of Oakley and found that every child who had used the city water supply during the period in which their enamel was undergoing calcification had mottled enamel on every surface of every permanent tooth. They found also that every child in school who lived outside the town was free from this defect. Following this dental survey, the town decided to change its water supply. McKay, who for years has studied this subject, had suggested in a previous report that a statistical study be made in some community six or seven years after the water supply had been changed. The opportunity came, and in February of this year he reexamined the children of Oakley, assisted by Dr.

Smith, who also took part in the survey made in 1925. If something in the water used by these children during the period of calcification of the enamel caused the defect, the proof should be found in children born about the time the water supply was changed and who at the time of the reexamination had some of their permanent teeth. Such evidence was found at the recent reexamination. The children of Oakley were placed in groups according to their age. In those children born at the time of the change of the water supply or shortly after, there was not a single tooth found that was mottled. Practically all of a few children who at the time of the change of water were from 6 months to 1½ years of age were without mottled enamel. Few children who were from 2½ to 3½ years of age at the time of the change of the water showed any mottled enamel, but every one of the children who were 4½ years of age at the time of the change of the water supply had mottling of the enamel in some degree. The same was true of the children who were from 5½ to 7½ years of age when the change of water was made. One pupil was 11½ years old when the change of the water supply was made. All the teeth of this pupil, excepting the third molars, had been formed during the time this community used the old water supply, and all these teeth were typically mottled. The third molars, which were formed after the change in water, were calcified normally. In the interval of years between the two examinations in this community by McKay, investigators had established the relation between fluorine in the water and the occurrence of mottled enamel. The danger line in the fluorine content of water had been found to be about two parts per million. The former water supply of Oakley when examined by H. V. Churchill was found to contain six parts of fluorine per million; the new water supply has been found to contain less than one-half part per million. This experience completes the proof, McKay believes, of the relation between fluorine in the water and the presence of mottled enamel. It furthermore provides a definite procedure whereby communities that have had to face this problem may protect their children in the future.

Association News

MEDICAL BROADCAST FOR THE WEEK American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9:15 to 9:20 a. m., Chicago daylight saving time, which is one hour faster than central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

July 18. Seashore vs. City Vacations.
July 20. Frozen Assets.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

July 22. Some Facts About Moles.

1. Dean, H. T.: Distribution of Mottled Enamel in the United States, Pub. Health Rep. 48:703 (June 23) 1933.

2. McKay, F. S.: Mottled Enamel: The Prevention of Its Further Production Through a Change of the Water Supply at Oakley, Ida., J. Am. Dent. A. 20:1137 (July) 1933.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Deaths from Scorpion Sting.—According to *Arizona Public Health News*, within the last two years six deaths from scorpion sting have been reported to the state board of health. Nearly all the six deaths occurred in children. In Arizona there are two species of scorpion, the desert scorpion and the so-called rock or mountain scorpion. The danger apparently depends on the kind from which the sting is received, its size and the age of the person stung.

CALIFORNIA

Personal.—Dr. John L. Pomeroy, health officer of Los Angeles County, was elected president of the Western Branch of the American Public Health Association at its fourth annual meeting in Pasadena, May 29-31.—Dr. Frank B. Galbraith has been appointed health officer of Alameda, succeeding Dr. Ralph W. Sanders, and Dr. Lloyd G. Tyler, San Rafael, health officer of San Anselmo, replacing Dr. Malcolm S. Edgar.

New Milk Ordinance.—A milk ordinance approved for San Francisco, May 15, reduces the maximum bacterial count in market milk from 150,000 nonpathogenic bacteria per millimeter to a maximum of 50,000. Other provisions of the ordinance effect changes in the selling and distribution of milk, which must be from cows that have been tuberculin tested, and in the pasteurization of milk and cream. It also establishes classification in the grading of milk. No herd shall be considered tuberculosis free if the reaction to the test is more than 10 per cent of the entire herd. Following the signing of the ordinance by the mayor, May 25, an injunction was granted the Natural Milk Producers' Association, halting enforcement of it.

FLORIDA

State Board Elects.—Dr. Corbett E. Tumlin, Miami, was named president of the state board of medical examiners at a meeting, June 12, succeeding Dr. Carl A. Williams, St. Petersburg. Dr. Simeon E. Driskell, Jacksonville, was elected vice president, and Dr. William M. Rowlett, Tampa, reelected secretary. Dr. Nicholas A. Baltzell, Marianna, resigned from the board to become a member of the state board of health.

Society News.—At a meeting of the Dade County Medical Society, April 7, Dr. Taylor Lewis, Miami, among others, spoke on "Human Sterilization as a Eugenic Measure." Dr. Gerard Raap, Miami, addressed the society, May 5, on "Abnormalities of the Vertebral Bodies."—A symposium on obstetrics was conducted before the Duval County Medical Society, April 4, by Drs. James D. Pasco, Ferdinand Richards, Samuel R. Norris and Anasa D. Stollenwerck, all of Jacksonville.—Dr. John J. Kindred, DeLand, addressed the Volusia County Medical Society in DeLand, April 11, on mental diseases.—Dr. Jack Halton, Sarasota, was installed as president of the Florida Railway Surgeons Association at its annual meeting in Hollywood, May 1, and Dr. Walter C. Page, Cocoa, named president-elect.—Robert M. Yerkes, D.Sc., New Haven, Conn., addressed the Tuberculosis Association of Duval County, May 12, on "Primate Tuberculosis."—Dr. William C. Blake, Tampa, was elected president of the Florida Heart Association in Jacksonville, May 19, and Dr. George L. Cook, Tampa, secretary.—Speakers before recent meetings of the DeSoto-Hardee-Highlands County Medical Society at Sebring and Avon Park included Drs. Emory W. Bitzer, Tampa, and Merle C. Kayton, Wauchula, on essential hypertension and sinusitis, respectively.

GEORGIA

Donors of Medical Library Honored.—The donors of the A. W. Calhoun Medical Library, Atlanta, were honored at a dinner, May 31, at the Atlanta Athletic Club, commemorating the tenth anniversary of the founding of the library in memory of the late Dr. Abner W. Calhoun. The donors are Mesdames A. W. Calhoun, Stuart Witham, Junius Oglesby and Dr. F. Phinizy Calhoun. Dr. Stewart R. Roberts made an address on "The Books of Medicine and the Calhoun Library." The

library, which is maintained in Emory Hospital, contains about 16,000 volumes and served 24,000 readers last year.

Emory Alumni Clinics.—The Alumni Clinic Week of Emory University School of Medicine, Atlanta, was held, June 6-9, at Grady Hospital, in conjunction with the Georgia State Board of Health and the U. S. Public Health Service Clinic on Venereal Diseases. Surgical clinics were held each morning and afternoon and a program of lectures was in progress throughout the day. Among more than fifty lecturers were Drs. Stewart R. Roberts, on "Present-Day Views of Digitalis: Its Actions and Use in Heart Disease"; Frank Lee Bivings, "Infantile Eczema"; Allen H. Bunce, "Treatment of Secondary Anemia," and Mark S. Dougherty, Jr., "Cirrhosis of the Liver." Dr. Weldon E. Person was chairman of the program committee.

ILLINOIS

Appointments to State Department of Registration.—Mr. John J. Hallihan has been appointed director of the state department of registration and education, succeeding Mr. Michael F. Walsh, and Eugene R. Schwartz as superintendent of registration, replacing Mr. Paul B. Johnson. Mr. Stanley Kiflewsky, Chicago, succeeds Mr. J. E. Edwards as chief inspector.

Chicago

Annual Golf Prize.—On his retirement as president of the Chicago Medical Society, June 21, Dr. Herman L. Kretschmer presented a silver cup to the Chicago Medical Society to perpetuate the memory of Dr. J. Warren Vanderslice, who died, Dec. 24, 1932. The winner of an annual golf tournament will have his name inscribed on the cup and may keep it for one year. Physicians eligible for the competition will be the officers and trustees and past presidents of the Chicago Medical Society and members of the council and officers of the branches of the society. The game is to be played between the annual election and Labor Day and will be arranged by a committee consisting of the president-elect, secretary and three members of the council.

Dr. Hektoen Becomes Professor Emeritus.—Dr. Ludvig Hektoen retired as professor of pathology, Division of Biological Sciences, University of Chicago, July 1, becoming professor emeritus. Dr. Hektoen, who is 70 years of age, has been professor and head of the department of pathology at the university since 1901. From 1895 to 1898 he was professor of morbid anatomy at Rush Medical College. Since that time he has been professor of pathology at the college. He occupied a similar position with the College of Physicians and Surgeons of Chicago from 1892 to 1894. Dr. Hektoen has been director of the John McCormick Institute for Infectious Diseases since 1902 and editor of the *Journal of Infectious Diseases* since 1904 and of the *Archives of Pathology* since 1926. He was three times chairman of the division of medical sciences of the National Research Council. Societies of which he has been president include the Chicago Medical Society, 1919-1921; Chicago Pathological Society, 1898-1902; Association of American Pathologists and Bacteriologists, 1901; Society of American Bacteriologists, 1929; Society of Immunologists, 1927; Institute of Medicine of Chicago, 1929. In 1909 he was vice president of the American Association for the Advancement of Science and for several years has been chairman of the Committee on Scientific Research of the American Medical Association.

INDIANA

Personal.—Dr. Howard Willard Byrn, Terre Haute, received the Ravdin Medal, given each year to the member of the graduating class who has made the highest average through the four years of the medical course at the University of Indiana School of Medicine, Indianapolis. The medal is given by Dr. Marcus Ravdin, Evansville.

Gift to Library.—More than 600 medical books from the library of the late Dr. Lewis P. Drayer have been given to the library of St. Joseph's Hospital, Fort Wayne, by his daughter, Mrs. Scott Snyder. The gift increases the hospital's library to nearly 1,500 volumes, the majority of which have been donated recently by Fort Wayne physicians, newspapers reported.

Society News.—Dr. Harold M. Trusler, Indianapolis, addressed the Franklin-Fayette County Medical Society, June 13, on "Reconstruction of Burns and Scar Tissue."—Dr. Robert M. Moore, Indianapolis, was guest speaker at a recent meeting of the Carroll County Medical Society, Burlington, on "The Failing Heart."—The Gibson County Medical Society was addressed at Princeton, June 12, by Drs. Karl S. Strickland, Owensville, on "Diphtheria and Its Complications" and Martin L. Arthur, Patoka, "Differential Diagnosis of Scarlet Fever."

Dr. Harvey Appointed State Health Commissioner.—Dr. Verne K. Harvey, Indianapolis, has been appointed state health commissioner, succeeding Dr. John H. Hare, Indianapolis, newspapers reported. When the state board of health was recently replaced by an advisory committee, Dr. Hare was named executive secretary to carry on the executive work of the department, succeeding Dr. William F. King, who had been health commissioner since 1922. Dr. Harvey is 34 years of age and a 1929 graduate of the Indiana University School of Medicine, Indianapolis. He has been associated with the state board of health as epidemiologist. Dr. Hare will replace Dr. Charles E. Laughlin as superintendent of the Evansville State Hospital. The latter had occupied the position since 1903.

Anniversary of Medical Practice Observed.—Ninety-two photographs of physicians who had practiced in the county during the last hundred years were presented to the Wabash County Medical Society at its meeting in Wabash, June 7, by Dr. James T. Biggerstaff, who has been doing historical research for the society. These photographs were the only ones available of the 212 physicians who had practiced in the county during the century of medical practice, the anniversary of which was observed by the medical society at this meeting. The photographs are now hanging in the reception room at the Wabash County Hospital. Dr. John H. Reed, Logansport, made the presentation address on "The Valley of Vision of a Century of the Practitioners of Medicine and Surgery in Wabash County in 100 Years." The first medical practitioner located in Wabash County in May, 1833.

IOWA

Executive Secretary Appointed.—At the recent annual session of the Iowa State Medical Society, through an amendment to the by-laws, the position of executive secretary was created. Mrs. Dorothy McCarthy was appointed to the position for one year, beginning June 1.

Dinner to Dr. Bierring.—The Des Moines Academy of Medicine and Polk County Medical Society gave a banquet and reception in honor of Dr. Walter L. Bierring, Des Moines, President-Elect of the American Medical Association, June 26, at the Wakonda Club. Dr. Fred Moore served as toastmaster and addresses were made by Dr. Bierring and Major-Gen. Merritte W. Ireland, Washington, D. C., former surgeon general of the U. S. Army. Drs. Everett D. Plass, Iowa City, and Thomas F. Thornton, Waterloo, who with Dr. Moore were members of the House of Delegates at the Milwaukee session of the American Medical Association, attended the banquet.

Society News.—Dr. Thomas F. Suchomel, Cedar Rapids, was elected chairman of the Military Surgeons Club of the Iowa State Medical Society at its annual meeting, May 10.—Dr. Howard E. Campbell, Anita, gave a paper on "External Injuries to the Abdominal Viscera" before the Cass County Medical Society in Atlantic, May 16.—The Chickasaw County Medical Society heard Dr. Jesse Carl Painter, Dubuque, discuss "Childhood Types of Tuberculosis" at a meeting, recently, and Dr. Edward C. Nowak, New Hampton, "Eye Injuries."—Dr. Harold H. Webb, Ottumwa, was among the speakers before the Davis County Medical Society in Bloomfield, May 26; his subject was "Nontuberculous Conditions of the Chest."—A symposium on allergy was presented before the Woodbury County Medical Society, recently, by Drs. Louis J. Frank and Thomas R. Gittins, Sioux City. Dr. Joseph C. Ohlmacher, Vermilion, S. D., addressed the society, May 25, on kidney diseases.—A paper, prepared and read by Dr. J. D. Miles, Crawfordville, in September, 1874, was presented before the Tri-County Medical Society (Henry, Jefferson and Washington) by Dr. Clyde A. Boice, Washington; its title was "Compound Fracture of the Tibia and Fibula, Treated by the Antiseptic Method."—Dr. Daniel J. Glomset, Des Moines, addressed the Marshall County Medical Society, June 6, on nephritis.

KANSAS

Society News.—Dr. Arthur E. Hertzler, Halstead, addressed the Butler-Greenwood Counties Medical Society in El Dorado, May 12, on "Dysmenorrhea with Particular Relation to Endocrine Origin."—The Clay County Medical Society sponsored a clinic on skin diseases by Drs. Paul F. Stookey and Hubert Parker, Kansas City, Mo., May 10; in the evening, the physicians lectured on "Treatment of Syphilis" and "Pharmacology of Antisyphilitic Drugs," respectively.—Dr. Henry N. Tihen, Wichita, addressed the Sedgwick County Medical Society, May 16, on his observation of European practice, under the title of "Medical Medley."—At a meeting of the Shawnee County Medical Society, May 1, the speakers were Drs. Clar-

ence K. Schaffer, Topeka, on "Hemicranial Atrophy" and William C. Menninger, Topeka, "Role of Financial Losses in the Precipitation of Mental Illness."

MARYLAND

Personal.—The National University of Ireland, Dublin, conferred the honorary degree of doctor of science on Dr. Dean Lewis, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, recently.—Dr. Howard A. Kelly, emeritus professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, received the honorary degree of doctor of laws from Washington College, Chestertown, recently.

Spotted Fever.—Twenty-eight cases with five fatalities from spotted fever occurred in Maryland from the middle of May to the latter part of June. Ten cases were reported in Carroll County, seven in Anne Arundel County, two each in Dorchester and Somerset counties, and one each from Baltimore, Caroline, Frederick, Howard, Kent, Montgomery and Wicomico counties. Two deaths occurred in Carroll County, two in Anne Arundel County and one in Somerset County. Rocky Mountain spotted fever was first recognized in Maryland in 1929, when seven cases, diagnosed as typhus fever, were investigated. From 1930 to 1932, inclusive, 127 cases of spotted fever were reported to the state department of health, 104 with sixteen deaths from the counties, and 23 cases with five deaths from Baltimore. One of the deaths attributed to the counties occurred in Washington, but the disease was contracted in Maryland.

MICHIGAN

Veteran Physicians Guests of Honor.—Ten graduates of the Detroit College of Medicine and Surgery were guests of honor at the annual banquet and clinic, June 5, in recognition of their having spent fifty years in the practice of medicine. The honor guests of their alma mater were Drs. Charles G. Jennings, who received his degree in 1879; Hugo Erichsen, Birmingham, 1882; Walter J. Cree, 1883; Lewis E. Maire, 1881; B. C. H. Spencer, Rochester, 1881; John A. Wessinger, Ann Arbor, 1882; Hiram Holden, Trenton, 1883; John McKinlock, Chicago, 1883; William H. German, Chicago, 1883, and Stanley G. Miner, Detroit, 1882. The program of the alumni reunion consisted of clinics by Drs. George W. Crile, Cleveland, and Walter C. Alvarez, Rochester, Minn., on thyroid diseases and recent discoveries in the physiology of the gastrointestinal tract, respectively. Dr. Crile was the dinner speaker, on "Orthogenesis and the Power and Infirmities of Man."

NEBRASKA

Society News.—Drs. Samuel M. Hibbard and Arthur H. Haynes, Sabetha, Kan., addressed the Richardson County Medical Society, Falls City, May 18, on eclampsia and urinary infections of children, respectively.—Speakers at a meeting of the Cedar, Dakota, Dixon, Thurston and Wayne Counties Medical Society, Newcastle, June 15, were Drs. John D. Lutton, Laurel, "Trichomonas Vaginalis Vaginitis"; Antonius A. Larsen, Homer, "Management of Obstetrics in the Home," and Paul F. Siman, Wayne, "Pneumonia."—Drs. Henry J. Lehnhoff, Lincoln, and Merton O. Arnold, St. Paul, addressed the Hall-Merrick-Howard County Medical Society, Grand Island, May 18, on "Pathologic Changes of the Myocardium" and "Renal Obstruction," respectively.

Creighton University News.—Faculty changes at Creighton University School of Medicine include six appointments and ten promotions. The appointment of Dr. Augustus G. Pohlman, former dean of the University of South Dakota School of Medicine, as professor and head of the department of anatomy, was noted in THE JOURNAL, June 10. The following others are announced: Drs. George K. Fair, Charles J. Fogarty, William J. Egan and William M. Dendinger, assistants in medicine, and John E. Courtney, assistant in surgery. Those who were promoted are:

Dr. James F. Kelly, professor of roentgenology and head of the department.

Dr. Arthur C. Johnson, assistant professor of surgery.

Dr. John F. Gardiner, assistant professor of medicine.

Dr. William H. Schmitz, assistant professor of urology.

Drs. Norman H. Atwood and Edward S. Maloney, instructors in medicine.

Dr. Maynard M. Greenberg, instructor in ophthalmology.

Dr. Clarence S. Moran, instructor in pathology.

Drs. Leo P. Coakley and Frederic M. Watke, instructors in otolaryngology.

A portrait of the late Dr. Hermann von W. Schulte, dean of the medical school from 1917 till his death in 1932, was presented recently to the university by the medical faculty. Dr. Bryan M. Riley, professor and head of the department of medicine, made the presentation speech and President Patrick

J. Mahan, S.J., the speech of acceptance for the university. The three upper classes in the medical school also presented a set of anatomic models as a memorial to Dr. Schulte.

NEW JERSEY

Personal.—Dr. Jesse B. Thompson, Atlantic City, recently entertained at dinner twenty alumni of the class of 1888 of the University of Pennsylvania School of Medicine.—Dr. William A. Pinkerton, Bayonne, was recently named head of the obstetric department of Bayonne Hospital.—Dr. Pellegrino A. D'Acerno, Union City, was elected president of the New Jersey Italian State Medical Society, at a meeting, May 26, in Newark.

NEW YORK

Dinner to Dr. Flaherty.—The Onondaga County Medical Society recently sponsored a testimonial dinner to Dr. Frederick H. Flaherty, Syracuse, in honor of his succession to the presidency of the Medical Society of the State of New York. Among speakers were Drs. Arthur J. Bedell, Albany, president-elect of the state society; Thomas P. Farmer, Syracuse, president of the county society; Thomas Parran, Jr., Albany, state health officer; Arthur W. Booth, Elmira, and Grant C. Madill, Ogdensburg, and Lorenz Brosnan, legal counsel for the state society.

New York City

Society News.—Dr. Ariel W. George, Boston, addressed the New York Roentgen Society, May 15, on "Medicolegal Expert Testimony as It Applies to the Roentgenologist."—Dr. Ronald T. Grant, London, England, addressed the section of medicine of the New York Academy of Medicine, in May, on "Prognosis of Heart Disease."—The International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists celebrated the fifth anniversary of its founding, May 21, at a reception at the home of the president, Dr. Jacob M. Gershberg.

A Million Children Immunized.—The immunization of the millionth child in New York against diphtheria was recently made the occasion of a celebration in Central Park, in which medical and health leaders and 5,000 school children took part. Dr. William H. Park, director of laboratories in the New York City Department of Health, immunized the millionth child at the Meinhard Memorial Health Center and Dr. Béla Schick, "the first of the second million." At the park celebration which followed, Mayor O'Brien, Health Commissioner Shirley W. Wynne and Drs. Park and Schick made addresses, after which children of various national groups presented folk dances. It was explained that from 1916, when diphtheria immunization was first made available in the United States, until 1929, only 260,000 children in the city had received the treatment. In the latter year the Diphtheria Prevention Commission began its intensive three-year campaign, at the end of which 522,063 more children had been treated. Since the dissolution of the committee the health department has continued the drive, which brought the total to a million. There remain about 700,000 unimmunized children in the city, the department reports. A similar celebration marking the immunization of the four hundred thousandth child in Brooklyn was held in Prospect Park, June 24, the climax of a four weeks drive.

Historic Petition Found at Columbia.—The petition that led to the establishment of the College of Physicians and Surgeons of Columbia University has recently been found, after having been lost for 165 years, the New York Times reports. The document with several others was discovered in an old chest in the rear of the vaults under the Columbia University Library. Five physicians signed the petition: Samuel Clossy, Peter Middleton, James Smith, John Jones and Samuel Bard, the latter of whom was dean and later president of the medical school. The petition was addressed to the governors of Kings College, Aug. 4, 1767, and the school opened November 2 of the same year. It was suspended during the Revolutionary War and was reestablished in 1784 as the Columbia School of Medicine, but active teaching was not carried on until 1791, according to the archives. In 1814 the Columbia school was merged with the College of Physicians and Surgeons, which had been established in 1807. The first course of lectures given at the school was described thus in the petition:

It is proposed to give a Course of Lectures in the Winter Season upon each of the following Branches of Medicine, viz.: Anatomy by Doct. Samuel Clossy; Physiology and Pathology by Doct. Peter Middleton; The Theory and Practice of Physick by Doct. Samuel Bard; The Theory of Chirurgery with a Course of Operations upon the Human body by Doct. John Jones; Chemistry by Doct. James Smith with the Materia Medica.

The founders asked no emoluments for their services but did ask that "these professorships shall at least have all that exterior Dignity, and every honorary Mark of Respect, which is in your Power to bestow."

NORTH DAKOTA

Society News.—Drs. Joseph G. Parsons and Chester L. Oppegaard, Crookston, Minn., were guests at the annual meeting of the North Dakota Academy of Ophthalmology and Otolaryngology in Valley City, June 1. They presented a discussion of "Block Anesthesia in Otolaryngology." Dr. Henry O. Ruud, Grand Forks, was elected president and Dr. Frederick L. Wicks, Valley City, secretary. The fall meeting will be held at Rochester, Minn., in conjunction with the South Dakota academy.

OHIO

Rating Service Extended to Private Practice.—A plan recently adopted by the Cleveland Academy of Medicine for investigation of the financial condition of patients unable to meet full charges for medical service has now been placed at the disposal of any member of the academy who wishes to send patients for ratings. The patient will pay a fee of 50 cents to the bureau of social service, which is under the direction of a trained worker. The development of social service as an adjunct to the private practice of medicine is said to be unprecedented. The bureau plans also to advise families in preparing budgets to allow for the exigencies of illness.

Society News.—Dr. Frederick R. Crowgey, Salem, addressed the Columbiana County Medical Society, Lisbon, July 11, on "Correlation of Surgery with Medicine."—Physicians of four counties attended a meeting sponsored by the Defiance County Medical Society, Wauseon, June 16, at which speakers were Drs. Howard R. Hartman, Rochester, Minn., on treatment of duodenal ulcer, and Charles Mayo, Rochester, chronic and acute intussusception, and J. Howard Brown, D.Sc., Baltimore, relation of milk to disease.—Dr. Frank W. Harrah, Columbus, addressed the Fayette County Medical Society, Washington Courthouse, June 1, on significance of abdominal pain.—Drs. Donald F. McGrath and Raymond C. King, Toledo, addressed the Auglaize County Medical Society, Minster, June 7, on "Analgesia and Anesthesia During Labor" and "Common Obstetrical Complications," respectively.—Dr. Louis Mark, Columbus, addressed the Belmont County Medical Society, Bellaire, June 1, on "The Role of Surgery in Tuberculosis."—Dr. John H. J. Upham, Columbus, addressed the Jefferson County Medical Society, Steubenville, May 26, on "Costs of Medical Care."

PENNSYLVANIA

An Exhibit of Hobbies.—The final meeting for the season of the Allegheny County Medical Society, Pittsburgh, June 20, was distinguished by an exhibit of the hobbies of members. Various types of art work were shown by Drs. Joseph H. Barach, Homer W. Grimm, Howard H. Permar, John G. Wurtz, John Chornyak, Warren A. Wolf and Walter E. Brown. Photography was displayed by Drs. Morris A. Hersenson and Daniel F. Jackson; collections of books and book-bindings by Drs. James D. Heard, Ralph V. Robinson, John A. Hagemann and Norman R. Goldsmith. Dr. James R. Johnston exhibited a collection of letters; Drs. Mortimer Cohen and John K. Musgrave, woodcraft; Drs. William J. McGregor and Daniel A. Atkinson, ballistic displays; Dr. Benjamin Levant, music; Dr. Harry C. Westervelt, antique glass; Dr. Victor W. Cowan, butterflies; Dr. Hagemann, unique walking sticks; Dr. William H. Gardner, monographs, and Dr. Johanna T. Baltrusaitis, minerals and petrified wood. Dr. Harry N. Malone displayed a post-revolutionary copy of "The Vermont Union" and sketches by Dr. Albert G. Walter, a famous Pittsburgh surgeon who died in 1876. On the formal program Dr. Thomas B. Carroll made a farewell address as outgoing president; Russell J. Ferguson, associate professor of history, University of Pittsburgh, discussed "Contributions of the Physician to the Social and Cultural Development of Society"; Rev. Clarence E. Macartney, pastor of the First Presbyterian Church of Pittsburgh, "St. Paul's Thorn in the Flesh and His Physician" and Dr. Theodore Diller, history of the society.

Philadelphia

H. K. Mulford Honored.—The Philadelphia College of Pharmacy and Science at its one hundred and eleventh commencement, June 7, conferred the honorary degree of master in pharmacy (honoris causa) on Henry K. Mulford, director of biological and research laboratories of the National Drug Company, Philadelphia. Mr. Mulford was the founder and for many years directing head of the H. K. Mulford Company and is now president of the Mulford Colloid Laboratories in addition to his connection with the National Drug Company. He was graduated from the Philadelphia College of Pharmacy and Science in 1887.

TENNESSEE

Society News.—Dr. George W. Crile, Cleveland, addressed the Davidson County Medical Society, Nashville, May 19, on "Diseases Peculiar to Civilized Men."—Dr. John Henry Schroder, Cincinnati, spoke on "Clinical Aspects of Indigestion" before the Gibson County Medical Society, May 22, and Dr. Robert C. Derivaux, Nashville, "Heart and Blood Vessels in Diabetes."—Dr. James M. Waters, Walland, addressed the Blount County Medical Society, June 27, on "Heredity Versus Environment."—Dr. Richmond McKinney, Memphis, presented a paper on "Treatment of Malignant Disease of the Tonsils by Radium and X-Rays" and Drs. Russell A. Hennessey and Alfred D. Mason, Jr., one on "Traumatic Injuries of the Urinary Tract," before the Memphis and Shelby County Medical Society, June 6.—Dr. James M. J. Vandegriff, Fountain City, addressed the Knox County Medical Society, Knoxville, June 20, on "Trench Mouth."—The Washington County Medical Society held a special meeting, June 1, in Johnson City, marking the thirtieth anniversary of the granting of its charter. Dr. Joe T. Smith, Knoxville, was the guest speaker, giving an address on the thymus gland. Drs. Edwin A. Long and William J. Matthews, Johnson City, reviewed the society's history.

TEXAS

Personal.—Dr. Joseph Herbert Page, Houston, has been named full time health officer of Harris County.—Dr. Ellen D. Furey has accepted a position on the teaching staff of the department of pathology of the University of Minnesota School of Medicine, Minneapolis, it is reported. She recently resigned as adjunct professor of pathology at the University of Texas School of Medicine, Galveston, to do graduate work at Minnesota.

Gift to Medical School.—A collection of the late Dr. N. N. Allen, an early professor of surgery at the state medical college at Galveston, was recently presented to the institution by the physician's daughter, Mrs. George Osborne, Hempstead. The collection, which includes books, photographs and letters, will be used in writing a history of the college and of medicine during the early days of Texas, newspapers reported. Dr. Allen served as professor of surgery at the medical school both while it was a part of Soule College of Chapel Hill and after it became a part of the University of Texas.

Society News.—Dr. John A. McIntosh, San Antonio, was elected president of the Texas Neurological Society at the annual meeting in Fort Worth; Dr. Everett C. Fox, Dallas, of the Texas Dermatological Society; Dr. Clark A. Wilcox, Wichita Falls, of the Texas Radiological Society and Dr. William A. Lee, Denison, of the Texas Railway Surgeons' Association.—The Lamb County Medical Society was recently formed at a meeting in Littlefield, with Drs. James R. Coen and John G. Little, both of Littlefield, as president and secretary, respectively.—The North Plains Medical Society, composed of Sherman, Moore, Dallam and Hartley counties, was recently organized with Dr. Evans P. Stewart, Stratford, as president, and Dr. Victor R. Moore, Dalhart, secretary.

Health at San Antonio.—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million for the week ended July 1 indicate that the highest mortality rate (18.3) appears for San Antonio and the rate for the group of cities as a whole, 10.2. The mortality rate for San Antonio for the corresponding period last year was 10.6 and for the group of cities, 10.1. The annual rate for eighty-five cities for the twenty-six weeks of 1933 was 11.5, as against a rate of 12 for the corresponding period of 1932. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

WASHINGTON

Personal.—Dr. John S. McBride has been reappointed health commissioner of Seattle for a term of five years; he completed the unexpired term of Dr. Ernest T. Hanley.—Dr. Harry Eugene Allen, Seattle, has been appointed chief medical adviser to the state department of labor and industries.—Dr. Elmer Hill, Walla Walla, has been appointed physician to the state penitentiary.—Dr. Erval R. Coffey of the U. S. Public Health Service has been appointed secretary of the state department of health by Governor Martin.—Dr. William N. Keller, Tacoma, has succeeded Dr. Charles E. Taylor as superintendent of the Western Washington State Hospital, Fort Steilacoom. He occupied the position from 1914 to 1922.

WYOMING

Tri-State Meeting Postponed.—A joint meeting of the state medical societies of Wyoming, Utah and Idaho, which was to have been held at Yellowstone Park, August 6-8, has been postponed till 1934. Wyoming will have no state meeting this year. The present officers will continue until the next annual meeting of the association.

GENERAL

Results of Special Examinations.—Forty applicants passed the examination of the American Board of Obstetrics and Gynecology held at the Milwaukee General Hospital, Milwaukee, June 13. Three were conditioned and one failed.

Detroit Wins Health Conservation Award.—Detroit won first prize for health conservation among cities of more than 500,000 population in the annual health conservation contest conducted by the United States Chamber of Commerce. Winners in other population groups were: Cincinnati, cities from 250,000 to 500,000; Syracuse, N. Y., and New Haven, Conn., tied among cities from 100,000 to 250,000; East Orange, N. J., 50,000 to 100,000; Brookline, Mass., 20,000 to 50,000, and Lodi, Calif., under 20,000.

Visit to French Spas.—One hundred American physicians have been invited to visit French thermal and climatic resorts as guests of the French government, July 21 to August 23. The number includes wives of members of the party. The group will have a private train at its disposal in France and is to be officially entertained in the various spas. Information may be obtained from Dr. David J. Kaliski, 70 East Eighty-Third Street, New York, who will be in charge of the party, which will leave New York, July 21, on the S. S. *Lafayette* and leave Le Havre for New York on the S. S. *Paris*, August 23.

Warning Against Impostor.—Complaints have recently reached the Better Business Bureau of St. Louis concerning a woman named Alice Bell, who claims to sell professional uniforms. She says she represents the Wear-Well Manufacturing Company, 1717 Olive Street, St. Louis, and collects down payments for uniforms which are never delivered. Investigation revealed that no such firm is known at the address given. The woman is reported to be between 35 and 40 years old, about 5 feet 6 inches tall and a brunette with brownish gray eyes. One report stated that she wore Oxford type eye glasses of white gold and that she has poor teeth. She tells the physician that she is not working on commission and it makes no difference whether her orders are large or small. It is reported that she may now be in Washington or Oregon.

Health Authorities Elect.—Dr. Frederick D. Stricker, Portland, Ore., state health officer and secretary of the Oregon State Medical Society, was elected president of the State and Provincial Health Authorities of North America at its forty-eighth annual conference in Washington, D. C., June 5-6. Dr. William Warwick, chief medical officer, Fredericton, New Brunswick, was made vice president, and Dr. Albert J. Chesley, state health officer of Minnesota, secretary, reelected. Dr. Edward H. Cary, Dallas, Texas, then President of the American Medical Association, was among the speakers on "Relations of the Private Physician to the Health Department," and Dr. Dean Lewis, Baltimore, then President-Elect of the Association, "The Attitude of the Medical Profession Toward the Rural Health Unit," and Surg. Gen. Robert U. Patterson, U. S. Army, "Army Responsibility for Civilian Conservation Corps." Following this meeting was the conference of state and territorial health officers with the U. S. Public Health Service. Speakers included Drs. Goldsborough F. McGinnes, Richmond, on "Recent Diphtheria Studies in Virginia," and Allen W. Freeman, Baltimore, "A Plan for Tuberculosis Control."

Bequests and Donations.—The following bequests and donations have recently been announced:

River Crest Preventorium of the Kensington Dispensary for Treatment of Tuberculosis, Philadelphia, will eventually receive \$105,000 from the estate of Oscar L. Long.

Methodist Episcopal Hospital, \$40,000; St. Vincent's Hospital, \$2,000, and the James Whitcomb Riley Hospital for Children, the residue of the estate after a number of other bequests have been made, by the will of Edmund Zoller; all the institutions are in Indianapolis.

Montefiore, Mount Sinai and Beth Israel hospitals, New York, \$7,500 each by the will of the late Isaac Marks, Mount Vernon, N. Y., and Lebanon Hospital and the New York Dispensary, \$5,000 each.

Episcopal Hospital and American Oncologic Hospital, Philadelphia, \$3,000 and \$2,000, respectively, by the will of Catherine B. Davis.

Presbyterian Hospital, Philadelphia, \$5,000 for an endowed bed, under the will of Mrs. Elizabeth W. Hildeburn.

St. Luke's and Roosevelt hospitals, New York, \$10,000 each to establish free beds for "persons of gentle birth" who cannot afford hospital care.

Nassau Hospital, Mineola, L. I., \$150,000 by the will of the late Ormond G. Smith.
 Northern Dispensary, New York, \$5,000 by the will of the late Col. Robert Lewis Harrison.
 Lenox Hill Hospital, New York, \$20,000, by the will of Rudolf A. Metz and \$25,000 by the will of Mrs. Anna Woerishoffer.
 St. Mary's, Brownsville and East New York, Beth Moses and Israel Zion hospitals, \$2,500 each; Jewish Hospital, \$5,000 by the will of Alois Lazansky. All the institutions are in Brooklyn.
 Children's Memorial Hospital, Chicago, \$10,000 from the estate of Mrs. Clara F. Bass.
 Grant Hospital, Chicago, \$10,000 from the estate of Mrs. Helen Moeng.
 Highland Park Hospital, Highland Park, Ill., \$25,000 from the estate of H. H. Hitchcock.
 Good Samaritan Hospital, Lexington, Ky., \$250,000 from the estate of H. L. Ott.
 New Haven Hospital, New Haven, Conn., \$75,000 from the estate of Temple.
 Mrs. Etta Almer.
 Mount Sinai Hospital, New York Homeopathic Medical College and Flower Hospital, Hospital for Joint Diseases, all of New York, \$5,000 each under the will of Leah J. Simpson.
 Stuyvesant Square Hospital, New York, \$200,000 by the will of William Halls, Jr.
 Pottsville and Good Samaritan hospitals, both of Pottsville, Pa., each \$5,000 by the will of the late Samuel Rowland, Schuylkill Haven, Pa.
 James Whitcomb Riley Hospital, Indianapolis, \$4,200 by the will of Kate S. Parker, and \$5,000 by the will of Susan D. Forst.
 Pekin Public Hospital, Pekin, Ill., \$5,000 from the estate of Mrs. Mary Van Orstrand.
 St. Vincent's Hospital, New York, \$65,000 from the estate of Miss Margaret Crane Hurlburt.

FOREIGN

Liverpool Limits Enrolment.—The dean of the Faculty of Medicine of the University of Liverpool, England, has informed the American Medical Association that there are no vacancies for foreign students. In addition, the dean stated that the number of local students would be limited.

Medicolegal Journal.—The *Medico-Legal and Criminological Review* has recently appeared as the official organ of the Medico-Legal Society of London. It will publish quarterly transactions of the society, original articles, abstracts, proceedings of foreign societies, reviews of books dealing with forensic medicine and criminology, and correspondence. Dr. Gerald M. J. Slot and Mr. Everard Dickson are joint editors.

New Hospital in North China.—The *Chinese Medical Journal* reports the opening of a new hospital at Wutueifu in north Shantung by the United Methodist Mission. The hospital has seventy beds and with its modern equipment, much of which was an innovation in the district, cost \$75,000 in local currency. It is about eighty miles in several directions from the nearest hospitals and members of its staff are the only physicians, with one exception, for the 3,000,000 or more inhabitants in the area served by the new institution.

Medal Awarded.—Dr. Saul Adler, professor of parasitology at the Hebrew University in Jerusalem, received the Chalmers Gold Medal of the Royal Society of Tropical Medicine and Hygiene of England, at a meeting of the society's council, June 15, according to the *New York Times*. The honor was given to Dr. Adler in recognition of his work as director of the kala-azar commission sponsored by the society and the university in 1930-1932 in Italy and Malta. He recently received the Laveran Medal of the Société de Pathologie Exotique of France for the same work. A graduate of Leeds University, England, Dr. Adler was engaged in research at Sierra Leone, Africa, before going to Hebrew University in 1924.

Personal.—Dr. Edwin Matthew, Edinburgh, was recently elected to represent the Royal College of Physicians of Edinburgh on the General Council of Medical Education and Registration of the United Kingdom for a term of five years.—Dr. Edward Mellanby has resigned from the chair of pharmacology at University of Sheffield to accept the Sheld chair of pharmacology in the University of Cambridge.—Dr. Alban Köhler, Wiesbaden, Germany, received the Rieder Gold Medal of the German Roentgen Society at its meeting in April. The medal has been awarded previously to the late Guido Holzknecht, Vienna, and Gösta Forssell, Stockholm.—Dr. Geoffrey Hadfield, pathologist of the Royal Free Hospital in London, has been appointed to the chair of pathology at the University of Bristol to succeed Prof. I. Walker Hall.—Dr. Wilhelm His, University of Berlin, received the Carl Ludwig Medal for 1933. The medal is awarded every year by the German Society for Cardiac Research for outstanding services in research on the circulation.

Deaths in Other Countries

Juliano Moreira, general director of the Psychiatric Institute of Rio de Janeiro; founder and permanent president of the Brazilian Society of Psychiatry, Neurology and Legal Medicine; honorary member of scientific societies in many parts of the world; delegate from Brazil to numerous international medical congresses; died, May 2; aged 60.

Government Services

Physicians in Conservation Camps

Nine hundred and fifty-nine physicians have been assigned to the work of rendering medical care and treatment to 240,514 men in the Civilian Conservation Forestry Camps and Army Reconditioning Camps. The number includes 472 members of the Medical Reserve Corps, 126 army medical officers, 203 naval medical officers, 82 physicians on full time contract basis and 76 on part time contract. Officials of the War Department estimate that 200 more physicians will be required as soon as a total of 300,000 men in camps has been reached. Nine hundred camps are now in operation out of a total of 1,639 planned. Officers of the Medical Reserve Corps with the rank of lieutenant or captain and other physicians desiring such service should make application to the commanding general of the corps area in which they live. Below is a list of corps areas and states included in each:

First Corps Area.—Headquarters, Army Base, Boston 9, Mass. States included: Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut.
Second Corps Area.—Headquarters, Governors Island, New York. States included: New Jersey, Delaware and New York.
Third Corps Area.—Headquarters, U. S. Postoffice and Court House, Baltimore, Md. States included: Pennsylvania, Maryland, Virginia and the District of Columbia.
Fourth Corps Area.—Headquarters, Fort McPherson, Georgia. States included: North Carolina, South Carolina, Georgia, Florida, Alabama, Tennessee, Mississippi and Louisiana.
Fifth Corps Area.—Headquarters, Fort Hayes, Columbus, Ohio. States included: Ohio, West Virginia, Indiana and Kentucky.
Sixth Corps Area.—Headquarters, 1819 West Pershing Road, Chicago, Ill. States included: Illinois, Michigan, Wisconsin, Post of Jefferson Barracks, Missouri, and Arcadia Target Range, Arcadia, Mo.
Seventh Corps Area.—Headquarters, Baird Building, Omaha, Neb. States included: Missouri, Kansas, Arkansas, Iowa, Nebraska, Minnesota, North Dakota and South Dakota.
Eighth Corps Area.—Headquarters, Fort Sam Houston, San Antonio, Texas. States included: Texas, Oklahoma, Colorado, New Mexico, Wyoming and parts of Arizona.
Ninth Corps Area.—Headquarters, Presidio of San Francisco, Calif. States included: Washington, Oregon, Idaho, Montana, Utah, Nevada, California and portion of Arizona.

Army Personals

Lieut. Col. Charles W. Haverkamp, Fitzsimons General Hospital, will proceed to his home and await retirement, for the convenience of the government.

Major Michael G. Healy, relieved at the School of Aviation Medicine, Randolph Field, Texas, and assigned for duty in the Hawaiian Department.

Major Patrick F. McGuire, Fort Sam Houston, Texas, will proceed to his home and await retirement, for the convenience of the government.

Col. Levy M. Hathaway, ordered to proceed to his home to await retirement, for the convenience of the government.

Col. Harold W. Jones, relieved at Fort Sam Houston, Texas, and assigned to the Hawaiian Department.

Col. Edward B. Vedder was to proceed to his home about June 22 to await retirement, for the convenience of the government.

Lieut. Col. Guy V. Rukke, having been found disqualified for the duties of a colonel in the medical corps by reason of disability incident to the service, his retirement with the rank of colonel is announced.

Major Francis W. Gusties, on completion of his present tour of foreign service in the Canal Zone, is assigned to Fort Bragg, N. C.

Major John C. Woodland, on completion of his present tour of service in the Canal Zone, is assigned to Army and Navy General Hospital, Hot Springs National Park, Ark.

New Editor of Naval Journal

Commander Louis H. Roddis, U. S. Navy Medical Corps, has been ordered to the Bureau of Medicine and Surgery to take charge of the division of publications, succeeding Lieut. Comdr. John Harper. In this capacity he will be editor of the *Naval Medical Bulletin*.

Change of Station in the Navy

Capt. John F. Murphy, from command of Navy Hospital, Charleston, S. C., to Navy Yard, Philadelphia.

Lieut. Comdr. Martin Donelson, from Navy Hospital, Great Lakes, to U. S. S. *Lexington*.

Lieut. Comdr. Lewis W. Johnson, from Navy Hospital, Great Lakes, Ill., to U. S. S. *Louisville*.

Lieut. Comdr. James B. Moloney, from U. S. S. *Louisville*, to Navy Hospital, Mare Island.

Lieut. Comdr. William P. Mull, from U. S. S. *Mississippi* to Navy Dispensary, Washington, D. C.

Lieut. David O. Zearbaugh, from U. S. S. *Patoka* to U. S. S. *Arizona*.

Comdr. William E. Eaton, from U. S. S. *Lexington* to Naval Hospital, Newport, R. I.

Comdr. Carleton I. Wood, from Naval Hospital, Great Lakes, Ill., to U. S. S. *Mississippi*.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 24, 1933.

Is Health Insurance Becoming a Dole?

In his presidential address to the Section of Preventive Medicine, Sir Henry Brackenbury, chairman of the council of the British Medical Association, asked: "Is it possible that the national health insurance scheme is becoming not primarily a method of securing medical advice for the insured but primarily a machine for doling out to them small sums of money week by week or month by month?" "Today, more than ever," said Sir Henry, "I find public attention concentrated on the cash benefits which may be claimed rather than on the medical attention. To a not inconsiderable degree the national health insurance system is in danger of becoming a gigantic machine for the distribution of shillings and only secondarily a beneficent medical service. I suggest that it is necessary and that it is time that these two aspects of the scheme should be separated." The insurance scheme was intended to make provision for medical attention for all manual workers and the less highly paid nonmanual workers but, owing to unemployment and the consequent failure of the necessary contributions from employer and employed, a steadily increasing number of workers is passing out of the scheme. "Must we not be concerned whether national health insurance is not beginning to fail in its national purpose?" he asked. "I suggest that when growing out of the national health insurance scheme there is developed a general medical service for the nation, it will be essential, and by no means difficult, to provide for the inclusion of those who are no longer able to make any individual contribution."

In previous letters the demand by socialists for "a general medical service" for all, which would be free and include every form of medical treatment, private, special and hospital, has been described. There was great danger of complete socialization of the profession when the socialist government held office. But Sir Henry Brackenbury evidently refers to the scheme brought forward by the British Medical Association, which did preserve some features of private practice and was suggested in order to avoid something worse. The position was discussed in *THE JOURNAL*, April 8, page 1120. The great defect of the national health insurance act is that it is socialistic and therefore manifests the viciousness inherent in all socialism. The selfishness of human nature is the rock on which the finance of all socialistic schemes breaks. There is no efficient check on the unemployed, who by means of exaggerating trivial complaints can convert insurance benefit into a dole. Sometime ago the ministry of health had to complain that the finances of the insurance system were endangered. Even without embarking on "the general medical service" it is probable that this country, the prosperity of which has been seriously impaired by over-taxation for socialistic purposes, will have to find more money for medical socialism. Similarly to the abuse of health insurance, but to a much more serious extent, insurance against unemployment has largely become a dole, which is burdening struggling industries and so producing more unemployment—the vicious circle of socialism.

Payment for Treatment of Accident Cases

In the house of lords, Lord Moynihan moved the second reading of the road traffic emergency treatment bill. He said that the physicians who rendered first aid in automobile accidents received in a large number of cases neither acknowledgment of their services nor payment. The cost to them of rendering this treatment was considerable. He hoped that it was not neces-

sary to remind the house of lords of the immense amount of gratuitous service rendered by physicians in this country. About 60 per cent of the work he had done during his own professional life had been unrewarded, and he was in no way exceptional in that. The medical profession was unanimous as to the injustice done to physicians who rendered emergency treatment. It was estimated that there were 35,000 cases of emergency treatment given in the outpatient departments of hospitals during the year at a cost of \$60,000. Not a cent of that sum was returned to the hospitals. The bill proposed that the maximum fee payable for treatment should be \$15. There were 2,800,000 automobile licenses issued in the country today and if 50 cents was added either to the premium charged by the insurance companies or to the price of the driver's license a sum more than sufficient, even including administrative expenses, would be available for the payments he was asking. The objection to payment of the physician and the hospital from funds so derived could be due only to prejudice, and prejudice here, as so often in other directions, was only the emotional reaction of ignorance to truth.

A large number of lords supported the measure. The bill was read a second time. The Earl of Plymouth then moved that it be referred to the same select committee to which the road accidents compensation bill already stood referred and that Lord Moynihan be added to the committee. The motion was agreed to.

Population of England About to Decline

The momentous fact that after extraordinary expansion in the past century the population of England is rapidly approaching a maximum and then an inevitable decline has attracted little notice. The fact that an increase is still going on shuts people's eyes to the fact that the present birth rate is insufficient to maintain the present population in future years. At the congress of the Royal Sanitary Institute, Prof. A. M. Carr-Saunders, a statistician, pointed out that the population of this country will cease to increase in 1940, and possibly before then, and will subsequently decline. He said that since the Domesday survey, at the end of the eleventh century, estimates for every succeeding century showed increases interrupted only by temporary catastrophes. It can be proved that the death rate will presently exceed the birth rate, and that the population will begin to decrease without any further decline in the fertility of married women—that is to say, in the size of the family. There is no longer "a replacement birth rate." The number of children born within the last five years, who in twenty years should form the 20-25 years age group, does not equal the number now in that group. Moreover, some of them will die before reaching the age of 20. The important point is that the population will cease to increase and will then decline, even if there is no further decrease in the size of the family. But the size of the family decreases every year. If emigration were again to attain its pre-1929 level, a decline would set in before 1940. Emigration on this level from 1929 to 1940 would mean a drop of population by a million at the end of that period. Professor Carr-Saunders complained that there is a complete failure to appreciate the situation. He has seen plans which visualize a population during the next half century arrived at by projecting the continuance of the growth of the last fifty years. In one case a large expenditure has been incurred to supply water for a population that will never exist.

Blood Transfusion in London

At the annual congress of the Royal Institute of Public Health a discussion took place on blood transfusion. In London about 400 members are newly enrolled annually in the Red Cross Transfusion Service and 250 are lost, of which 80 per cent are due to pressure by relatives, colleagues and employers. By extolling the donor as a hero, the press did the service much

harm. Mr. Geoffrey Keynes said that the discovery that sodium citrate was an anticoagulant and nontoxic led to the adoption of transfusion as a common therapeutic measure. It was still the method of choice after twenty years' use. Although the citrate was baled for rigors, it was admitted that some patients had them no matter what method of transfusion was used. Rigors might be minimized by not allowing the blood to fall below body temperature and by injecting slowly; it should take half an hour to inject 600 cc. The blood group of every donor should be determined every year or two to make certain that it did not alter. The direct test should be made between the donor's blood and the patient's serum wherever practicable. Universal donors should not be called on indiscriminately for patients of all groups, or the supply of them would be exhausted. Except in great urgency, hospitals or individuals using the service should group the blood of the patient before asking for the donor.

Dr. H. F. Brewer had found males and females between the ages of 18 and 65 acceptable as donors. He regarded any old tuberculous disorder as a contraindication. The hemoglobin of a city dweller should not be below 94 per cent. A blood Wassermann test should be made as a routine, and malaria should be excluded. Protein-sensitive persons, such as those subject to asthma, hay fever or urticaria, were not suitable. Donation by a menstruating woman was not injurious, provided the period was normal. The minimum safe interval between donations of an average quantity of blood (from 400 to 700 cc.) appeared to be three months for men and four months for women. Donors should not resume the upright position for at least an hour after service. Any lag in the recovery of the hemoglobin figure, which usually took from seven to fourteen days, was best treated by administration of iron and occasionally by addition of liver and kidney to the diet.

Condition of the Masses in Great Britain

In the discussion at the International Labor Conference, held at Geneva, on the proposal for a forty-hour week in industry Sir James Lithgow (representative of the employers of Great Britain) gave some remarkable facts on the condition of the masses in Great Britain, in spite of the prolonged industrial depression. He knew from personal contact with public officials, physicians and other social workers that, tragic as was the moral aspect of unemployment, none of the unemployed were in a state even bordering on actual want. An unemployed worker of average family responsibilities had today at least as much purchasing power as had the unskilled worker in full employment twenty years ago. Put otherwise, he was receiving today as much money as the unskilled worker in full employment in other countries who was his industrial competitor. Sir James Lithgow did not mention that this was possible only because of taxation so severe as to be unprecedented in this country and never known in any country, or that taxation had now reached and even passed its limit, the well-to-do being so taxed that they are gradually disappearing and, what is worse, the capital of the country being encroached on.

The British Medical Association and Ship Surgeons

The Medico-Political Committee of the British Medical Association has had the interests of ship surgeons under consideration since last October, when a subcommittee was appointed to go into the matter. It has now presented its report, which shows that the rates of pay for surgeons with the smaller companies varies from \$90 to \$110 a month, the pay ceasing on completion of the voyage. The surgeons are permitted private practice among the passengers and are allowed to charge fees on a prescribed scale. On one important line, passengers pay \$1.25 per visit, and the largest amount chargeable to a passenger during a voyage, save in exceptional cases, is \$75. Representations have been made to the subcommittee that the

pay is unduly low, but regard has to be paid to the facts that shipping is depressed and that the companies have no difficulty in securing surgeons, some of whom engage for reasons of health or for change of scene. It is therefore considered that this is not a propitious time to make representations as to the rate of pay. Another matter considered is that the captain has power to require the surgeon to submit his private accounts before presenting them to patients. It had been contended that this was undignified. But it has to be recognized that the captain is in full legal control of all matters connected with the ship while at sea. Although the subcommittee agreed that the practice was undesirable, no specific example of hardship had been brought to its notice. It was therefore recommended that no action be taken on this matter at present. It was agreed that the possibility should be explored of securing the addition of a representative of ship surgeons to the National Maritime Board, a statutory body which regulates the pay and conditions of service of those afloat. Heretofore all grades of shipping employees except ship surgeons have been represented on it.

The Economic Crisis and Physicians

The economic crisis is resting heavily, throughout France, on the medical profession. The unemployment aid given to workmen is not applicable to members of the liberal professions (physicians, lawyers, artists), their fate, in the eyes of a government impregnated with socialism, being regarded as much less important than that of manual workers. As a result, misery and want have entered the homes of many physicians, especially those who have children. The sanatoriums, which, up to 1931, were filled with patients, are half empty. The economic crisis, as affecting the physicians, is due to many causes. First there is an excess of physicians in France, as in all other civilized countries. To this may be added the effects of demagogic laws, which, in the name of a philanthropy for which the public shows its gratitude only toward the deputies who voted for them, bear heavily on the physicians by placing the medical care of an increasing number of inhabitants in charge of the state, which grants a ridiculously low fee to the physicians who treat them. Finally there is strong competition from the foreign physicians practicing in France, with the result that the country can no longer assure French physicians a respectable living. In spite of the laws, France is still the country in which a foreign physician can most easily establish himself by defying the regulations. However, the minister of public health has decided to undertake a revision of the diplomas of dentists and of doctors of medicine, which must be deposited at the prefecture of each department by their holders in order to acquire the right to practice. Despite the register containing the names of those authorized to practice, there are a great many irregularities. Many irregular diplomas have been registered by incompetent employees. Many foreign physicians establish themselves by merely placing a physician's sign on their door without offering to deposit their diploma, which would no doubt not be accepted, and a long time elapses before such a situation is revealed, in spite of the vigilance of the medical syndicates. Hence a ministerial decree has announced that a revision of all registrations of diplomas is to be made. Only the physicians who hold a diploma of a French faculty of medicine are relieved of this duty. The holders of foreign diplomas must present themselves at the prefecture of the department in which they practice and exhibit their diploma. Later the owners of houses in which any physician is practicing must supply the prefecture with a list of the names. Physicians who are practicing medicine under illegal conditions can be expelled from the country.

The question has been recently brought sharply to the fore as a result of measures adopted in Germany against the Jews, most of those who had to leave their country having taken refuge in France. Among these immigrants are many eminent Jewish physicians. A professorial chair has been created at the Collège de France for the eminent mathematician Einstein, but it is impossible for France to repeat too often this generous gesture. It is impossible to accord to Jewish physicians from Germany the right to practice in France, for that right is denied in Germany to the holders of a French diploma. The medical journals contain many advertisements of Jewish physicians from Germany offering their services as assistants in the laboratories. They are not meeting with success. The situation of these unfortunate men is pitiable. Some of them are accepting work as low-salaried employees, while their wives are, in some instances, serving as domestics.

Inconveniences Due to Electrotherapeutic Apparatus

The installation of an electrotherapeutic cabinet in a building in which there are several renters, as often happens in large cities, may expose the practitioner to formal complaints lodged against him in the courts, by his neighbors. In several instances, neighbors have contended that rays emanating from radiologic apparatus passed through the walls and caused various disorders. The courts ordered inquiries made and then required the radiologists to enclose their cabinets in a booth with thick walls covered with sheets of lead. Now the devotees of wireless telephony complain that high frequency apparatus emits waves that disturb their radiotelephonic transmissions. At Amiens, a dealer in apparatus used in wireless telegraphy brought suit against a physician, alleging that, in giving diathermic treatments, he disturbed the wireless apparatus that he displayed to customers. Similar observations have been made about the electric plants located in the center of cities. These plants, however, are too important to close down to suit the pleasure of listeners-in on the radio. Greater severity, however, is being shown, as usual, toward the physicians, and the court of Amiens ordered the electrotherapeutist to take such action as was necessary to prevent the business of the dealer in wireless apparatus from being disturbed. The physician found it next to impossible to prevent such disturbance, so he was ordered to change his consultation hours.

The Eighty-Second Birthday of Professor d'Arsonval

Ceremonies were held in Paris, May 27-28, to celebrate the eighty-second birthday of Professor d'Arsonval. A reception was organized at the Hôtel-de-Ville by the municipal council, and a special session was held in the Great Hall of the Sorbonne, which was attended by the president of the republic and government officials. Addresses were delivered by delegates of the learned societies to which Professor d'Arsonval belongs or which were founded in application of his discoveries. Among the delegates was Professor Jelinek, who had come from Vienna for this purpose. The minister of public instruction presented the scientist with a large medal and in a charming speech traced his career of discoveries in electrophysics and biophysics, noting the industrial applications. The whole world is profiting today from the discoveries of d'Arsonval. The use of high frequency currents is often termed d'arsonvalization. Professor d'Arsonval responded to the eulogies with many witty allusions, in which he gave reminiscences of his childhood days. He said that he owed to Claude Bernard whatever measure of success he had attained and that the title of which he was most proud was that of préparator in the laboratory of the great physiologist. He praised a number of his pupils who had, he stated, outdistanced their master. He pointed to Mr. Georges Claude, who sat near him, and said "This man was my greatest discovery."

ITALY

(From Our Regular Correspondent)

April 30, 1933.

The National Council of Research

At its recent sessions, the Consiglio nazionale delle ricerche, presided over by Guglielmo Marconi, devoted itself to planning a program of research in biology, medicine and nutrition. It was decided that the committee on biology should organize a new biologic station for applied genetics, experimental embryology and the physiology of persons subjected to high pressures. The research will be distributed among various universities.

A special commission is dealing with the problems of alimantation. Investigations are under way to promote the knowledge of the chemical composition, the caloric value and the vitamin value of the foods produced in Italy. The basal metabolism of Italians according to age and sex is being studied. Research is being carried on to establish the alimentary requirements of children and adults, pregnant and nursing women, laborers and soldiers.

The committee on medicine will suspend for a year the epidemiologic studies on typhoid, since the practical application of the results secured are still experimental. The research on rheumatism will be developed, for this is an important problem.

The studies completed on ancylostomiasis have established, in addition to the existence of healthy carriers of *Ancylostoma*, also the possibility that the larvae may penetrate vegetable tissues and make certain vegetables vehicles of infection.

The Olympic committee will continue the research on athletes.

The program of the committee on medicine will include two new subjects; namely, an examination of the relation between bone changes and the parathyroids, and the research on the etiology of malaria, in which recent studies have postulated the existence of a filtrable form of specific parasites.

Bone Transplant in Vertebral Fractures

Fractures of the dorsolumbar and the lumbar vertebrae, with crushing of the vertebral bodies, often cause rigidity, pain and gibbosity. To prevent these sequels, Professor Pieri of Belluno has advised, since 1917, an operation consisting in the application of a bone transplant after the Albee method, as in the treatment of tuberculous spondylitis. In the last eight years, Professor Pieri has operated in eight cases of fracture of one or more vertebral bodies (from the twelfth dorsal to the third lumbar) with deformations. The operation was performed within not more than fifty days, at the most, of the trauma. The bone transplant was attached to the arches of the two healthy vertebrae above and of the two healthy vertebrae below the area of the fracture. Immobilization of the trunk in a plaster cast, for one month, followed. Then, for two months, an ordinary Sayre plaster corset was applied.

Dr. Di Prampero announced to the Società medico-chirurgica of Belluno the satisfactory results obtained in all the cases thus treated and presented two patients on whom he had operated, one operation dating back eight years.

Academy of Sciences of Apulia

The Accademia Pugliese di Scienze met recently at Bari under the chairmanship of Professor Gaifami of the University of Bari. Amoia announced the unusual finding of *Trichomonas vaginalis* in the male urethra. Only four such observations are reported in the literature. The speaker considered it premature to state whether *Trichomonas*, which is regarded by many as pathogenic in its more common localization (the vagina), is likewise pathogenic in the urethra—male or female. Attimonelli discussed the duration of immunity in persons who have had smallpox. Subjecting to smallpox vaccination ninety-four persons who contracted smallpox during the epi-

demic of 1919, he secured in 20 per cent of them the formation of a pustule, and in 16 per cent a papulovesicular reaction. In a few others he noted the formation of a small papule. The speaker raised the question as to whether all the persons who presented the positive vaccinal reaction had lost their immunity to smallpox, or whether the vaccinal reaction is to be regarded as an expression of cutaneous allergy.

The Riberi Prize

The Accademia di medicina di Turin has announced the conditions of competition for the fifteenth award of the Riberi prize, which amounts to 20,000 lire (\$1,150). Scientific work submitted must mark a distinct advance in medical knowledge. Both printed and typewritten works in Italian, Latin, French, English or German will be accepted. Printed works must have been published since 1927. If the prize is awarded to a typewritten work, it must be printed by the author within two years. The works must be sent to the Accademia di medicina di Turin not later than Dec. 31, 1934.

BUENOS AIRES

(From Our Regular Correspondent)

Malaria in Cordoba

The health authorities of Cordoba recently observed about 500 cases of malaria in the rural districts of Rio Primero in Cordoba. They are conducting an antimalarial campaign, including an investigation of the possible endemicity of malaria, and various preventive measures.

High Mountain Climbing

In an editorial in *THE JOURNAL*, Dec. 24, 1932, page 2187, mention was made of a telegram from Berlin to the *New York Times* concerning the climbing of Mount Aconcagua, situated in the province of Mendoza in Argentina at 7,010 meters, by a German expeditionary group. Several previous attempts to climb Aconcagua were successful. Its top was reached by M. Zurbriggen in 1897, by Stuart Vines and Lanti in 1897, by R. Helbling in 1906, by F. Reichert in 1906 and by Macdonald, Ryan and Cochrane in 1925. The top of Tupungato at 6,650 meters was reached by Stuart Vines and Zurbriggen in 1897 and by Reichert in 1912. Dr. Reichert of the University of Buenos Aires has climbed several mountains in Argentina reaching altitudes of more than 5,000 meters. For his book, "La Exploración de la Alta Cordillera de Mendoza," published in 1930, Dr. Reichert was awarded the second National Prize of Sciences.

The National Congress of Surgery

The fifth National Congress of Surgery will meet at Buenos Aires next October under the presidency of Dr. Enrique Finochietto. The subjects to be discussed are treatment of acute intestinal obstruction, by Drs. Delfor del Valle of Buenos Aires, and D. Pratt of Montevideo; treatment of fractures of the elbow, by Drs. N. Tagliavache of Buenos Aires, and L. Rezende Puech of São Paulo, and surgery in diabetes, by Dr. Rodriguez Villegas. The committee on organization has its headquarters in the offices of the Asociación Médica Argentina, Santa Fé 1171, Buenos Aires.

Protests Against Pay Clinics

The hospitals attract people more and more and the outpatient departments, attended by famous specialists with numerous assistants, are frequented by a large number of patients. As this service is gratuitous, the poor and even the rich have come to use it. Physicians complain, with reason, that this system is wrong. They are ready to give gratuitous service to those who cannot pay (only chiefs of service receive a small salary) but they feel that free service should not be

extended to persons of means. Hospitals are based on the principle of charity to those who come without verification of their nationality or residence, or whether or not they pay taxes. This system has had consequences: 1. It obliges physicians to assist gratuitously persons of means. 2. It competes with the private practitioners. 3. The municipal budget is charged with assistance to foreigners. 4. The public becomes accustomed to the maintenance of medical services as an obligatory governmental function. 5. The municipal budgets are insufficient to cover the expenses. Many physicians pay the expenses of their wards out of their own pockets in amounts varying between 300 and 2,000 pesos a month.

The clinical hospital of the university has established a scale of fees. Poor patients, whose cases are required for teaching, may be assisted gratuitously, but the others have to pay for each outpatient consultation, for every day of assistance and for operations, according to a scale that takes into account their salary, their civil status and the number of their children. This tariff has produced about 20,000 pesos a month, 70 per cent of which was turned over to the hospital. Unfortunately, the university has decided that 80 per cent of the fees must be given to it. This makes it certain that the wards will be filled with patients who do not pay and that donations will again be solicited as was done until last year.

The system of fees has worked satisfactorily for several years in the hospitals depending on the associated charities, supported by the national government. The municipal council proposed to establish a scale of fees for the nonpoor who attend municipal hospitals. Unfortunately the socialist majority objected, saying that it was wrong to demand proofs of poverty and that medical service should be gratuitous and directed by the government.

Undoubtedly the majority of the population prefers to be attended to by a physician of its own choice, who will offer more leisurely and more individual attention. As long as people prefer better assistance, the medical profession does not run the danger of seeing itself transformed into a governmental bureaucracy or a bureaucracy of insurance companies and mutual aid societies, although the latter are increasing in importance at the cost of the physicians, of whom there are already about 8,000 in the country for the 11,500,000 inhabitants, and 600 graduate every year.

Committee to Study the Climate and Mineral Waters of Argentina

The house of representatives passed a bill for the appointment of a national committee to study and report on the therapeutic properties of the mineral springs and climatic resorts of Argentina. The members of the committee are Drs. M. Sussini, B. A. Houssay, E. Herrero Ducloux, M. Castillo, M. Brandam and H. Corti, and J. Galmarini.

Recognition of Foreign Diplomas

According to the law, physicians holding diplomas from foreign universities cannot practice medicine in Argentina. According to the terms of a treaty, the validity of diplomas from Uruguay, Paraguay and Bolivia is recognized, but at various times the government has been requested to abrogate this treaty. Foreign physicians must have their diploma validated, paying 4,000 pesos, and pass an examination on thirty-eight subjects. Argentine physicians graduated abroad have to take only examinations at medical, surgical and obstetric clinics. There is a law that has been objected to. According to this law the government may recognize the diploma and the right to practice of foreigners under contract with the national authorities. It has happened that foreigners under contract to teach pathologic anatomy, bacteriology, embryology, physical chemistry and so on have invoked this right on the termination of their contract and practice medicine; this privilege has even been given to a physician who had broken his con-

tract. A curious case is the recent one of Dr. Schlanger, an Austrian radiologist, who was authorized to practice because a professor from La Plata made him a demonstrator and because Dr. Finochietto, a surgeon, employed him as radiologist. Such cases have given rise to many protests, which will result in a request to rescind the law.

New Professors

Dr. Nicanor Palacios Costa has been nominated professor of obstetrics in the School of Midwives. At the Faculty of Medicine of La Plata, Dr. A. Errecart has been nominated titular professor of otorhinolaryngology, and Dr. Orestes Adorni of medical pathology. At the Faculty of Medicine of Buenos Aires, Dr. A. Caeiro has been nominated assistant professor of operative medicine, Dr. O. Adorni of medical pathology, Dr. O. Ivanissevich at the surgical clinic, and Dr. A. D. Marenzi of biologic chemistry; the latter has worked with Folin in Boston.

Prizes

The first national prize of sciences for 1930 (30,000 pesos) has been given to Drs. Solé and Piñero Sorondo for their work on gastric ulcer. The third prize (10,000 pesos) has been divided between Dr. A. Battro for his study on coronary occlusion and Dr. A. Salaber for his thesis on the embryology of the female genital apparatus. The prize for the best work in medicine during the years 1931-1932 was given to Dr. Diez for his work on surgery of the sympathetic system.

Personals

Dr. Pedro Rojas, who was given a scholarship by the Rockefeller Foundation to study in Brussels in 1931, has been appointed professor of History at the Faculty of Medicine of Buenos Aires.

Drs. F. R. Ruiz, C. Weskamp and P. Ferrazzini have been appointed professors of pathologic anatomy, ophthalmology and obstetrics, respectively, at the Faculty of Medicine of Rosario.

Drs. J. B. Señorans, Buenos Aires, Pierre Janet, Paris, and H. Rossello and E. Blanco Acevedo, Montevideo, have been appointed national and foreign honorary academicians, respectively, of the Academy of Medicine of Buenos Aires. Drs. H. García Lagos and P. Barcia, Montevideo, have been appointed foreign correspondents of the same academy.

JAPAN

(From Our Regular Correspondent)

May 15, 1933.

The Overproduction of Medical Graduates

Nineteen medical universities and eleven medical colleges have had 3,143 medical graduates this year. The deaths of physicians last year numbered 933, and those who gave up practice, 23. The real actual increase of physicians during the twelve months was 2,187, which is a record increase of physicians in this country. It is due to the sudden increase in the number of medical schools in 1928 as the after-effects of prosperous times. The first graduates came from the new schools this April. There was 1 physician to 1,297 people in 1930. The average annual increase of population for the five years following 1925 was 884,052, while the average increase of physicians was 891 for those years; that is, there was 1 physician to 1,078 of population. This year the proportion was greatly changed. If this increase in graduates continues, in ten years there will be 1 physician to every 500 people. Far sighted men are earnestly emphasizing the need of emigration to the continent, especially to the new republic of Manchukuo.

Periodic Medical Examinations

The relationship of physicians and the family has gradually changed. The physician formerly was truly a family physician. People ran to his door to consult about trouble, both physical

and mental. He was an adviser to the family. This custom is now seldom seen in this country. Dr. K. Miyajima, a well known medical expert, asks in the *Medical News*, What is the best way to regain the old confidence of the family in the physician? He says the only way is to establish periodic medical examination of all members of the family. Some intelligent people already feel the necessity of it, though the majority have to be awakened to this need. The good results of such an examination on the part of the patient are obvious. As for the physician, this examination will benefit him greatly, but it requires deliberate observation and attention in executing the examination. The examinee may be in good health, but the observations may be useful from the standpoint of statistical research. The examinations should start in infancy, if possible, or be made during the developing period twice a year. The physician should also learn the habits, pleasures and occupation of the examinee. Such knowledge of the patient is certain to establish the confidence of the sick person in the physician. He also says that the fee should be sufficient, for the examination requires much time, equipment and hard work.

"Uncaging" the Licensed Prostitute

The licensed prostitute in Japan has been confined to restricted districts since 1900, being prohibited from leaving those districts even for a walk without permission from the police station in charge. The police were not generous with their permits, unless unavoidable reasons were proved. This state of "caged" living has long been a source of criticism, and it is to be abolished on the 21st of this month. Licensed prostitutes will then be free to leave the restricted districts whenever they wish without permission from the police if only the brothel host consents. There is, of course, some apprehension concerning their immoral practice outside their quarters, with some fear of difficulty in preventing venereal disease. While this "uncaging" may tend to encourage an increase in the number of prostitutes, from the point of view of recognizing individual liberty it has received the approval of the public. The Christian Women Purification Crusade is reported to have renewed its plans to abolish the brothels in order to release about 22,000 prostitutes from slavery, asserting that there will be no increase in venereal disease.

The International Red Cross Conference

It has been decided to hold the International Red Cross Conference in October, 1934, in Tokyo. It is reported that sixty-four countries and fifty-eight Red Cross societies will send delegates.

Increase in Dentists Attached to Public Schools

The school dental law was promulgated in 1931, and the school dental service regulations were announced by the education office in 1932. Complete control all over the country in this line of hygiene has been made. In spite of the business depression, the employment of school dentists has rapidly increased. According to an investigation in April, 3,619 primary schools had employed 2,788 dentists. In the middle grade schools, 719 schools had employed 690 dentists. Last year 126,699 yen was spent in the primary schools and 14,965 yen in the middle grade schools for this purpose.

Health Insurance

Along with government health insurance there have been formed two private health insurance schemes, one between a city medical association and some large factories, the other between a prefectural medical association and some factories in one of the chief manufacturing centers, for the first time. According to the agreement, all members of the associations are to be panel doctors, and all the operatives in factories and their families have free choice of physicians. The fee will be paid by the factory proprietors in advance for the patients, who are required to return the sum needed for the treatment out of

their wages little by little. The spreading tendency of sick benefit associations shows the change in medical practice in this country. But in these two cases, medical treatment is neither to be limited treatment nor treatment at cost but is to be treatment as is usual with ordinary patients.

Another sick benefit association, or health insurance, which claims a low fee and treatment at cost, has appeared in not a few towns and farming villages and is supported by the industrial guild. This guild is a powerful and widespread industrial organization with its own hospitals and clinics.

A Hereditary Eye Disease

At the meeting of the Japan Ophthalmologic Society recently in Tokyo, Prof. Dr. B. Hata, of the Okayama Medical University reported that since 1928 he had examined about 25,300 cases of eye disease, among which he found 311 cases of malignant pigment degeneration of the retina, a kind of cataract that begins at adolescence with night blindness, and ends in blindness in a score or so of years. Among the 311 there were 161 blind. Going back to their ancestors, he investigated the relation of this disease to marriage and heredity. Fifty-four cases were found to have occurred among consanguineous marriages. Of these fifty-four patients, forty-four had parents who were related by blood; 167 had ancestors who had suffered from the same disease. No such transmission was found in forty-four cases. He concluded from this research that the disease was transmitted by intermarriage or was hereditary.

Increase in Crime and Suicides

A sharp increase in the number of crimes committed in this country is indicated by official figures obtained from the bureau of police. In all, 1,181,705 cases of violation of law were recorded by the police in 1931, with an annual increase of about 120,000 cases during the preceding years. There were 769 cases of manslaughter in 1930 and 952 in 1932. Of offenses in 1931 the most conspicuous increases were in cases of theft and false pretense. In 1929, 2,412 robberies in which either threats or weapons played a part were committed, and in 1930 a total of 2,282. In the following year, however, a slight decrease was noted, the figure dropping to 2,198. The number of minor thefts committed in 1930 totaled 540,310, and in the following year increased to 584,542. Illegal acts committed by sexual perverts in 1930 numbered 3,039; in 1931 this figure increased to 3,409. Violation of the laws on gambling in 1931 totaled 26,964, with an increase of approximately 3,000 cases compared with 1930. Figures pertaining to suicides and attempted suicides in the Tokyo metropolitan police area during 1932 were 2,357, which shows an increase of 507 compared with the previous year. In 1932, 1,401 men and 965 women committed or attempted suicide; in 1931, 1,160 men and 690 women. In 1932, poison was used by 516 men and 476 women; drowning, by 231 men and 98 women; hanging, by 271 men and 94 women; jumping before trains, by 226 men and 50 women.

The Society for the Encouragement of Science

A society for encouraging the promotion of all branches of science was formally organized this spring. The last session of the diet approved the government's annual subsidy of 750,000 yen. Besides, the emperor's subsidy was 1,500,000 yen. The total sum to be spent annually to encourage scientific research will amount to 5,000,000 yen. The honorary president of the society is Prince Chichibu, the younger brother of the emperor; the president is Viscount Admiral Saito, the prime minister, and the chief director is Dr. Joji Sakurai, D.Sc., president of the Imperial Academy. From medical circles, six councilors were appointed, including Dr. T. Kitajima, head of the Japan Medical Association. The society will begin work this autumn; its selection is said to be the result of careful deliberation by 110 councilors.

Marriages

JOSEPH GARBER COCKE, Birmingham, Ala., to Miss Violet D. Hoile at Columbus, Ga., June 5.

ERNEST HENRY WARNOCK to Miss Mary Frances Ogle, both of Indianapolis, May 20.

WILLIAM RIVES WILSON to Miss Elleda Bristol, both of Ansonia, Conn., May 20.

HERMAN B. KAUFMAN to Miss Ida Snewind, both of Youngstown, Ohio, June 11.

CLIFFORD L. CARTER to Miss Astrid Nygren, both of Chicago, June 7.

Deaths

George Eli Armstrong, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1877; emeritus professor of surgery at his alma mater; member and past president of the American Surgical Association; fellow and past president of the American College of Surgeons; past president of the Canadian Medical Association; served during the World War; aged 78; consulting surgeon to the Verdun Protestant Hospital, Montreal General Hospital and the Royal Victoria Hospital, where he died, May 25.

George Francis Suker @ Chicago; University of Michigan Medical School, Ann Arbor, 1892; Chairman of the Section on Ophthalmology, American Medical Association, 1930-1931; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Post-Graduate Hospital, Cook County Hospital, Grant Hospital and the Edward Hines, Jr., Hospital, Hines, Ill.; aged 63; died, July 2, of coronary sclerosis.

Gordon Moore Gibson @ Brooklyn; McGill University Faculty of Medicine, Montreal, Que., Canada, 1904; associate professor of obstetrics and gynecology, Long Island College Hospital; fellow of the American College of Surgeons; on the staffs of St. Peter's Hospital and the Huntington (N. Y.) Hospital; aged 51; died suddenly, June 17, of coronary thrombosis and arteriosclerosis.

Leo Brooks Rosenthal @ New York; Columbia University College of Physicians and Surgeons, New York, 1909; adjunct professor of internal medicine, New York Polyclinic Medical School and Hospital; aged 48; on the staffs of the People's Hospital and the Sydenham Hospital, where he died, June 18, of injuries received when he was struck by an automobile.

Faxton Eugene Gardner @ Fairlawn, N. J.; Université de Paris Faculté de médecine, 1904; clinical professor of dermatology and syphilology, New York Polyclinic Medical School and Hospital; member of the Medical Society of the State of New York; served during the World War; aged 55; died, June 21, in the Peekskill (N. Y.) Hospital.

Ernest Hamilton White, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1901; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; professor of otolaryngology at his alma mater; on the staff of the Royal Victoria Hospital; aged 55; died, June 15.

Archibald Clair Adams, Lima, Ohio; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1900; member of the Ohio State Medical Association; formerly county coroner; on the staffs of St. Rita's Hospital and the City Hospital; aged 58; died, June 15, of heart disease.

James Harry Ullrich @ Baltimore; Baltimore Medical College, 1897; associate professor of gastro-enterology, University of Maryland School of Medicine and College of Physicians and Surgeons; served during the World War; aged 58; died, June 27, in the University Hospital, of suppurative pancreatitis.

Clement Biddle @ Medical Inspector, Commander, U. S. Navy, retired, Philadelphia; Jefferson Medical College of Philadelphia, 1878; entered the Navy in 1878 and retired in 1908 on application after thirty years' service; served during the Spanish-American War; aged 78; died, June 5.

Ernest Sanford Jack, Melrose, Mass.; Harvard University Medical School, Boston, 1886; member of the Massachusetts Medical Society; on the staff of the Melrose Hospital; aged 72; died, May 17, of chronic nephritis, hypertension and cerebral hemorrhage.

George William Roberts, Spokane, Wash.; Medical College of Ohio, Cincinnati, 1884; member of the Washington State Medical Association; veteran of the Spanish-American War; aged 63; died, May 11, of bronchopneumonia and metastatic carcinoma.

William Cantine Gilley, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885; member of the Medical Society of the State of New York; aged 82; died, June 21, in St. Luke's Hospital, of heart disease.

Charles Huber, New York; Columbia University College of Physicians and Surgeons, New York, 1896; member of the Medical Society of the State of New York; on the staff of the Lenox Hill Hospital; aged 60; died, June 4, of cerebral hemorrhage.

Edward H. Whitcomb, St. Paul; Columbus (Ohio) Medical College, 1884; an affiliate Fellow of the American Medical Association; formerly county coroner; aged 71; on the staff of St. Joseph's Hospital, where he died, June 8, of cerebral glioma.

Raymond Coleman Hill, Rochester, N. Y.; Syracuse University College of Medicine, 1905; member of the Medical Society of the State of New York; on the staff of the Rochester State Hospital; aged 53; died, June 5, of heart disease.

Fred W. Vance, Mannington, W. Va.; Eclectic Medical Institute, Cincinnati, 1905; member of the West Virginia State Medical Association; formerly mayor of Mannington and member of the board of education; aged 59; died, May 20.

Frederick Lamont Gates, Cambridge, Mass.; Johns Hopkins University School of Medicine, Baltimore, 1913; lecturer on general physiology, Harvard University; aged 46; died, June 18, of a skull fracture, received in an accident.

Benjamin Emmett Graham, Gurley, Ala.; University of the South Medical Department, Sewanee, Tenn., 1894; past president of the Madison County Medical Society; aged 59; died, June 22, as the result of an automobile accident.

Robert Ira Busard Ⓢ Muskegon, Mich.; Northwestern University Medical School, Chicago, 1910; fellow of the American College of Surgeons; on the staff of the Hackley Hospital; aged 46; was killed, June 21, in an airplane accident.

Isaac Ward Sampsell, New York; Northwestern University Medical School, Chicago, 1900; member of the American Psychiatric Association and the Medical Society of the State of New York; aged 60; hanged himself, June 27.

Herbert William Newhall Ⓢ Lynn, Mass.; Harvard University Medical School, Boston, 1884; for eight years member of the school committee; aged 75; died, June 18, of coronary thrombosis, myocarditis and arteriosclerosis.

Clarence Erroll Wilson, Boise City, Okla.; State University of Iowa College of Medicine, Iowa City, 1910; member of the Oklahoma State Medical Association; aged 46; died, June 22, of a self-inflicted bullet wound.

James Flandreau Van Fleet Ⓢ New York; Fordham University School of Medicine, New York, 1918; on the staffs of the Nyack (N. Y.) Hospital and the Manhattan Eye, Ear and Throat Hospital; aged 42; died, June 5.

Robert Harold Coker, Tallahassee, Ala.; University of Alabama School of Medicine, 1915; member of the Medical Association of the State of Alabama; aged 40; died, June 17, in St. Margaret's Hospital, Montgomery.

Justin Thomas Smallwood, Worthington, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1908; member of the Minnesota State Medical Association; aged 50; died, May 24.

William Van Werden, Los Angeles; Rush Medical College, Chicago, 1885; member of the Iowa State Medical Society; aged 70; died, April 18, at the Iowa Methodist Hospital, Des Moines, of carcinoma of the liver.

Charles Edward Adams, Gastonia, N. C.; University of Maryland School of Medicine, Baltimore, 1878; member of the Medical Society of the State of North Carolina; aged 78; died, June 9, of angina pectoris.

Edward George Hayer Ⓢ Nanticoke, Pa.; Medico-Chirurgical College of Philadelphia, 1910; for many years on the staff of the Nanticoke Hospital; aged 50; died, June 20, in Belmar, N. J., of endocarditis.

Charles Bryant Clark, Cedar Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1893; member of the Iowa State Medical Society; aged 61; died, June 24, of subarachnoid hemorrhage.

John Williams Brown Ⓢ University of Virginia Department of Medicine, 1899; served during the World War, 1917-18; died, June 1, of poisoning, self administered.

Sydney Sumner De Beck, Franklin, Maine; University of Vermont College of Medicine, Burlington, 1887; member of the Maine Medical Association; aged 69; died, March 20, of heart disease.

Charles Edmund Carr, New York; Columbia University College of Physicians and Surgeons, New York, 1913; aged 50; died, May 17, in the Presbyterian Hospital, of pulmonary embolism.

William T. Mefford Ⓢ Riverside, Ill.; Cincinnati College of Medicine and Surgery, 1874; Medical College of Ohio, Cincinnati, 1880; aged 80; died, May 17, of uremia and chronic nephritis.

George Wesley Hinkle, Harvard, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1875; member of the Iowa State Medical Society; Civil War veteran; aged 83; died, May 13.

Lewis Fish, Fitchburg, Mass.; Baltimore Medical College, 1898; member of the Massachusetts Medical Society; on the staff of the Burbank Hospital; aged 62; died, June 3, of angina pectoris.

Guy Roland Anderson Ⓢ Barnesboro, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1899; formerly member and president of the school board; aged 59; died, June 17.

Luther Edgar Moore, Searcy, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1885; member of the Arkansas Medical Society; aged 72; died, June 4, of senility.

Albert S. Applewhite, Jackson, Miss.; Atlanta (Ga.) School of Medicine, 1908; member of the Mississippi State Medical Association; aged 63; died, June 6, of heart disease.

Silas Simeon Brown, Pittsburgh; Baltimore Medical College, 1893; aged 70; died suddenly, May 31, in a railway station at Little Falls, Minn., of cerebral hemorrhage.

Jacob S. Shoemaker Ⓢ New Lothrop, Mich.; University of Michigan Medical School, Ann Arbor, 1883; aged 78; died suddenly, June 20, of heart disease, at Cynthiana, Ky.

Joseph Octave Reaume, Windsor, Ont., Canada; Michigan College of Medicine, Detroit, 1885; Faculty of Medicine of Trinity College, Toronto, 1886; aged 77; died, June 13.

James Hughes Neff, Sullivan, Ind.; Kentucky School of Medicine, Louisville, 1890; member of the Indiana State Medical Association; aged 72; died, June 22, of nephritis.

John Hamilton Charters, Detroit; Saginaw (Mich.) Valley College, 1903; member of the Michigan State Medical Society; aged 54; died suddenly, June 22, of heart disease.

John Henry Linder, Socorro, N. M.; University of Louisville (Ky.) School of Medicine, 1909; aged 48; died, June 8, of a self-inflicted bullet wound in the head.

Amos Avery, Portland, Ore.; Long Island College Hospital, Brooklyn, 1899; aged 65; died, May 29, in the Portland Sanitarium, of cerebral hemorrhage.

Harry Melick Keller Ⓢ Hazleton, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1888; aged 66; died, May 27, of heart disease.

Magnus F. Stewart, Loveland, Colo.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1895; aged 62; died, April 30, of cerebral embolism.

Amelia Augenia Dranga Ⓢ Pittsburgh; Woman's Medical College of Pennsylvania, Philadelphia, 1897; aged 66; died, May 27, of heart disease.

Josiah Evans Cowles, Los Angeles; University of Maryland School of Medicine, Baltimore, 1880; aged 78; died, June 14, of heart disease.

James C. Littleton, Baltimore; University of Maryland School of Medicine, Baltimore, 1883; aged 85; died, June 9, of bronchopneumonia.

Jacob E. Nyquist, Duluth, Minn.; University of Minnesota Medical School, Minneapolis, 1905; aged 59; died, May 24, of gastric carcinoma.

William Daniel Cox, Strawberry Plains, Tenn.; Tennessee Medical College, Knoxville, 1900; aged 72; died, June 21, of angina pectoris.

Howard Girard Barton, Adelphi, Ohio; Ohio Medical University, Columbus, 1893; aged 69; died, June 8, of organic heart disease.

John Robert Durrett, Nelson, Mo.; Missouri Medical College, St. Louis, 1899; aged 59; died, May 27, of cerebral hemorrhage.

Byron Stillman Cranston, New London, Ohio; Baltimore Medical College, 1893; aged 64; died, June 13, of nephritis.

George L. Cornell, Rudyard, Mich.; Detroit College of Medicine, 1890; aged 68; died, June 6, of heart disease.

Bureau of Investigation

CURRIER'S TABLETS

Another "Patent Medicine" for Stomach Ulcers

During the past three or four years the country has been flooded with "patent medicines" sold for the alleged cure of stomach ulcers, hyperacidity and general gastric distress. Possibly the economic stress through which the country has been passing, with the resultant worry and mental depression has brought about an increased incidence of so-called gastric neuroses. There seems little doubt that gastric distress is widely prevalent. Persons thus afflicted have their condition still further aggravated by the "patent medicine" advertisements, either in newspapers or over the radio, that, like all "patent medicine" advertising, attempt to develop the fear complex—to make well people think they are sick and sick people think they are dangerously sick. The belief is implanted in the minds of the sufferers that they have peptic or duodenal ulcer, and they are led to believe that the only hope of escaping the operating table is to buy the particular "patent medicine" whose advertisements they happen to read or hear.

There are numerous preparations of the stomach-ulcer-cure type on the market. One of the first to be puffed was "Pfunder's Stomach Tablets," which came from Minneapolis. It was dealt with in an article in this department of *THE JOURNAL*, Dec. 1, 1928, and it was there shown that the tablets were essentially a mixture of bismuth subnitrate, magnesium oxide and baking soda. Then there was "Udga," which came from the same part of the country as Pfunder's and apparently had much the same composition. This was the subject of a brief item in the "Queries and Minor Notes" Department of *THE JOURNAL*, Feb. 15, 1930. A "patent medicine" advertised extensively for "heartburn, acid indigestion, sour stomach and gas" and rejoicing in the descriptive name "Tums for the Tummy," was found to be a mixture of chalk and sugar flavored with peppermint. It was the subject of a short article in this department of *THE JOURNAL*, May 23, 1931.

Judging from the number of inquiries received by the Bureau of Investigation, it would seem that one of the most widely exploited nostrums in the stomach-ulcer class at the present time is "Currier's Tablets," put out from Los Angeles. Currier's Tablets are advertised by that new boon to the nostrum exploiter, the radio, although some newspaper space has also been used. Those who write to Currier's Tablets, Inc., Los Angeles, to ask for further information regarding the product are sent a letter printed in imitation typewriting, stating that the tablets "are not merely a temporary relief, but are intended to stimulate the stomach to normal and overcome the cause." The recipient of the advertising is also told that the tablets sell for \$5 a bottle and that if at the end of fifteen days' use the patient is not satisfied that he is being benefited, he may return the balance of the tablets and the \$5 will be refunded. With the letter there comes an advertising sheet, one-half of which is devoted to the story of how Currier's Tablets were discovered; the other half is devoted mainly to testimonials. The story of the discovery is rather typical of "patent medicine" exploitation. It is to the effect that Roy G. Currier was a "tall, dejected, depressed, unhappy" man in 1911 who weighed "a mere 137 pounds" and was suffering from an "enlarged liver." Four years' "consistent treatments succeeded in reducing the liver to a normal size." But alas! "The shell of a man remains the same." His case was then diagnosed as duodenal ulcer. He took "Pounds and pounds of Baking Soda . . . Tons of Bismuth of Megnesia [sic!] . . . Gallons of Peppermint." Later Roy G. Currier decided to take upon himself "the responsibility of experimenting with HIS OWN life . . . HIS OWN health . . . HIS OWN STOMACH." With the aid of a "chemist friend" and "months of laboratory work," they developed the "secret compound"—Currier's Tablets. "The climax had been reached. Roy G. Currier was relieved of DUODENAL ULCERS . . . BY HIS OWN COMPOUND!!!" Thus was Currier's Tablets, Inc., formed, and the public is told that "under the protection of copyrights and patents Currier's Tablets became a byword . . . a boon

. . . a human necessity in the treatment of Hyperacidity, acidosis, gastritis, indigestion and Stomach Ulcers." It was, in short, a "marvelous remedy" that has "startled the medical world."

Another piece of advertising sent out by Currier's Tablets, Inc., is a sixteen-page pamphlet entitled "Facts." Two pages are devoted to giving the public some interesting misinformation regarding the human stomach. A picture is given of what is described as the "normal empty stomach" and shows it as an open bag! Mr. Currier's advertising men should look up their high-school physiology textbooks, even if they don't do further research. Two more pages of the pamphlet are devoted to proving that Currier's Tablets will cure stomach ulcers. Two X-ray pictures are reproduced showing a stomach ulcer before Currier's Tablets were taken and the same spot after they were taken. Then follow some pages of testimonials which are signed only with initials. One testimonial from a woman in Houston, Texas, stated that Currier's Tablets had helped her husband wonderfully, that an X-ray had shown a bad obstruction "which some said was cancer." The pernicious implications that are carried by advertising of this kind are obvious. Other testimonials describe how ulcers had been cured, how stomach troubles of thirty-five years ended, how gastritis was ended, etc.

Because of the number of inquiries received regarding Currier's Tablets, the A. M. A. Chemical Laboratory was asked to analyze the product. The chemists' report follows:

LABORATORY REPORT

"An original specimen of Currier's Tablets (Currier's Tablets, Inc., 1460 North Vine Street, Los Angeles, Calif.), Price \$5.00, was submitted to the A. M. A. Chemical Laboratory for examination. The label on the bottle bore the following statement:

"Currier's Tablets—Currier's Tablets can be obtained from Currier's Tablets, Incorporated, 1460-1462 N. Vine St., Los Angeles, Calif. Price, \$5.00. Contents 100 Tablets.

"Neutralizes gastric hyperacidity. In all cases where indicated these tablets have proven highly efficient."

"The jar contained 100 large cream-colored tablets possessing an aromatic odor resembling that of menthol. The average weight of each of 10 tablets, weighed individually, was 2.57 Gm. (approximately 40 grains) with a variation of 2.1 per cent above to 1.4 per cent below.

"Qualitative tests indicated the presence of starch, carbonates, nitrates, bismuth, magnesium, sodium, a substance resembling menthol, and acid insoluble material (talc). Calcium, mercury, antimony, potassium, chlorides, sulphates, phosphates, phenolphthalein, emodin-bearing drugs and alkaloids were not found.

"Quantitative determination yielded the following:

| | |
|---|---------------|
| "Loss on drying (100° C.)..... | 7.2 per cent |
| Loss over sulphuric acid..... | 2.7 per cent |
| Ash | 62.9 per cent |
| Acid insoluble material (talc)..... | 2.0 per cent |
| Bismuth (Bi+++) | 23.7 per cent |
| Magnesium (Mg++) | 16.3 per cent |
| Sodium (Na+) | 6.5 per cent |
| Carbon dioxide (CO ₂) | 11.8 per cent |
| Starch | 4.9 per cent |

"Based on the foregoing, it may be calculated that Currier's Tablets contain as essential ingredients:

| | |
|-----------------------------------|----------------|
| "Bismuth Subnitrate, U. S. P..... | 33.4 per cent |
| Magnesium Oxide, U. S. P..... | 31.1 per cent |
| Sodium Bicarbonate, U. S. P..... | 22.7 per cent" |

From the chemists' analysis, it appears that Currier's Tablets, the "secret compound" that was developed after "months of laboratory work" by Mr. Currier and his chemist friend, is essentially identical with the stock bismuth compound tablet that most of the large pharmaceutical houses sell. On the basis of the chemists' analysis, Currier's Tablets are approximately equivalent to a tablet having the following composition:

| | |
|--------------------------|-----------|
| Bismuth subnitrate | 13 grains |
| Magnesium oxide | 12 grains |
| Sodium bicarbonate | 9 grains |

Nearly all large pharmaceutical houses stock a tablet composed of bismuth subnitrate 10 grains, magnesium oxide 10 grains, and sodium bicarbonate 10 grains. These sell at \$1.85 a hundred. Currier's Tablets, Inc., sell for \$5 a hundred.

That Currier's Tablets will give temporary relief in cases of hyperacidity is, of course, obvious—but so will a little baking soda. It is equally true that the person with a gastritis, a peptic or a duodenal ulcer, or a beginning malignancy who attempts to treat himself with Currier's Tablets or any other "patent medicine" is running serious risks—how serious every physician realizes.

WILLARD'S TABLETS

Still Another Nostrum for Stomach Ulcer

"Willard's Tablets" are sold on the mail-order plan and marketed by the Willard Tablet Company of 215 West Randolph Street, Chicago. The Willard Tablet Company seems to be a trade name used by one Oscar E. Frieder. The company was incorporated in Delaware in May, 1932, and holds a license to operate in Illinois. The Willard Tablet Company shares its quarters with several other companies in which Oscar E. Frieder or other individuals by the name of Frieder are interested. According to the Willard Tablet Company's stationery, its telephone number is Franklin 1966. At the same address and using the same telephone number are the following concerns:

First United Finance Corporation
D. & M. Finance Company
Frieder Finance Association
Silver Mirror Company
Satis-Factory Shoe Company

At this point it is worth calling attention to the fact that part of the advertising follow-up material sent out by the Willard Tablet Company is a saffron-colored sheet entitled "Certificate of Deposit". This certifies that the Willard Tablet Company has placed on deposit with the First United Finance Corporation of Chicago "a sufficient sum of money to insure the prompt full cash refund" of all requests made by persons who state that after taking the Willard Tablets for fifteen days, they are not convinced that they have received any benefit. The same certificate also states that the First United Finance Corporation has examined all the letters that are used in testimonials in the Willard Tablets advertising. The president of the First United Finance Corporation is one Edward Frieder, while Oscar E. Frieder, president of the Willard Tablet Company, operating from the same address and using the same telephone number, is also said to be interested in the First United Finance Corporation.

The Willard Tablet Company has advertised somewhat extensively over that boon to the nostrum exploiter, the radio—for it is notorious that certain radio stations will accept "patent medicine" advertising that all but the lowest grade of newspapers and magazines will reject. Those who write in to the Willard concern receive a form letter in imitation typewriting, together with the usual number of testimonials, an order blank, the so-called Certificate of Deposit, and a twelve-page leaflet entitled "Willard's Message to Stomach Sufferers." According to the "Message" Willard's Tablets are a "quick, positive relief" for the following conditions:

| | |
|-----------------------------|--|
| Stomach and duodenal ulcers | Sour stomach |
| Gas pains | Hyperacidity |
| Indigestion | Belching |
| Constipation | Bloating |
| Acid dyspepsia | Loss of appetite |
| Heartburn | Upset stomach from alcoholic beverages |
| Bad breath | |

The correspondent is told in the form letter that:

"Willard's Tablets are a most wonderful preparation for the treatment of stomach ulcers and other disorders of the stomach due to or accompanied by acidity or food fermentation."

"Willard's Tablets afford the most reliable and dependable treatment for relief from stomach and duodenal ulcers, gas pains, indigestion, constipation, acid dyspepsia . . ." etc., etc.

One would get the impression from reading the Willard Tablets advertising that the tablets themselves were some remarkable formula unique in the history of therapeutics. The facts are Willard's Tablets are just another one of the antacid preparations containing, essentially, baking soda, bismuth subnitrate and magnesium oxide, a well-known combination that can be purchased in any drug store at a fraction of the price charged for the Willard nostrum.

Correspondence

'CONTINUED USE OF DIGITALIS IN PATIENTS WITH REGULAR RHYTHM'

To the Editor:—Any one who has interested himself in tracing back to original sources statements subsequently attributed to an author is struck by the frequency with which ideas are attributed to authors which are quite remote from the meaning of the statement originally made by this same author. Something of this sort will be found in the editorial in THE JOURNAL, June 3, entitled the "Continued Use of Digitalis in Patients with Regular Rhythm," in which the idea is attributed to me of having suggested that digitalis was a specific like thyroid in myxedema and liver in pernicious anemia. What I actually said was that, like these two forms of therapy, digitalis therapy, if started as suggested in my paper in THE JOURNAL, March 18, should be continued throughout life, which is entirely a different proposal from that attributed to me in the editorial referred to.

HENRY A. CHRISTIAN, M.D.,
Peter Bent Brigham Hospital,
Boston.

MORE ABOUT THE EFFECTS OF URETHRAL MEDICATION

To the Editor:—Concerning my answer to the California physician's query (THE JOURNAL, March 11, p. 766) against which Dr. Wolbarst voices a dissenting opinion (THE JOURNAL, May 13, p. 1558) I feel that his criticism deserves an answer. On the true facts rests the entire question of the prevention of posterior urethral infection. At the same time I admire Dr. Wolbarst and his work so greatly that I am loath to enter a discussion against his opinion.

His dissenting opinion is raised against my statement that, "if the anterior urethra is only partially filled with injected fluid, the tonic contraction of the cut-off muscle will prevent any of it passing into the posterior urethra, no matter how long it is retained." Against the truth of this statement he opposes an experience of over thirty years in urology. However, he has not raised a question that cannot be settled easily by any one who owns an anterior urethra, though he has placed(?) on his side "the experience of every urologist." That means that a lot of people who disagree with him probably are not urologists. Some thought they were.

Let us examine his "evidence." He says that when 2 or 3 drachms of fluid is injected into the urethra and held for some time only about 50 per cent of it is recovered, which "proves" that the rest seeped back through the cut-off muscle. Is this proof?

In his book he states that the anterior urethra is from 5½ to 6 inches long and will take a sound from 27 to 30 F. One is safer to take 27 F. as his figure for the estimation of capacity. It is interesting to note that it requires a 27 F. urethra of a length of approximately 8¼ inches to hold 3 drachms of fluid. Why attribute to seepage past a sphincter fluids that by the nature of things must be forced into the posterior urethra? One would like to say that the urethras were longer in New York than in the City of Brotherly Love, but he voids such a view by admitting that they just turn out standard sizes like the rest of our cities.

Obviously Dr. Wolbarst and my reply are not talking of the same thing. The reply spoke of a *partially* filled urethra. Any one who will make the following test will agree with its contention: Inject 5 or 6 cc. of a colored solution into the anterior urethra, have it retained for five minutes or even an hour, gently irrigate the anterior urethra to remove any of

the color, and then have the patient pass some urine in a glass. If the solution has "seeped" into the posterior urethra it will be in the first urine voided after such a test.

In some experimental work on the hydrogen ion concentration of the urethral secretion (Pelouze and Gonzales: *J. Urol.* 22:407 [Oct.] 1929) we on far more than 100 occasions injected 5 cc. of a 5 per cent sodium chloride solution into the anterior urethra, had it retained for five minutes, and carefully measured the expelled fluid. On not a single occasion was less than 5 cc. of fluid obtained.

Regarding Dr. Wolbarst's contention that the passage of fluids from a gonorrheal anterior urethra into a noninfected posterior urethra is a salutary thing, I can only say that in Philadelphia it usually precipitates posterior infection. I have seen enough cases from New York to know that this is not peculiar to my own city or practice.

P. S. PELOUZE, M.D., Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

BLEEDING TIME AND COAGULATION TIME

To the Editor:—Will you kindly tell me the essential difference between the "bleeding time" and the "coagulation time," and the standard tests for each. Most textbooks are not clear on the subject.

H. E. FRUIT, M.D., Fostoria, Ohio.

ANSWER.—The essential difference between the bleeding time and the coagulation time is that in the former test the factors of cephalin of the tissue juice, mechanical action of the blood platelets, and vessel permeability play a part. Bleeding time is the time required for a small cut to stop bleeding, while coagulation time is time between the withdrawal of blood from a vessel and its formation into a clot in vitro. The standard test for the bleeding time is the method of Duke. A small cut is made in the lobe of the ear with a cataract knife or sharp scalpel. The incision should be of such size that the drop of blood when taken up on filter paper will have the diameter of from 1 to 2 cm. Successive drops are blotted up every half minute until bleeding stops. The tissue must not be traumatized during the procedure. The normal time for this method is three minutes or less, or from two to six blots. In speaking of a standard test for the coagulation time, one must bear in mind that the time varies with the method employed. In all methods using blood from a skin cut, the admixture of tissue juice is a variable factor. Such tests are more apt to be unreliable than tests in which blood is drawn from a vein. There are, however, circumstances in which venipuncture is not possible. Under these circumstances, one of the methods employing capillary blood may be used; but the variable factors must be appreciated. The most simple of this group of tests is the glass slide method. The skin is punctured with a sharp instrument so that a free flow of blood is obtained. Several drops of blood are received on a carefully cleaned slide. A needle or pin is drawn through the drop at intervals of one minute. When shreds of fibrin cling to the needle or pin and are dragged along by it, coagulation has taken place. The normal time is seven minutes or less. Evaporation must be prevented by suspending the slide on glass rods above filter paper moistened with warm water in a petri dish.

The standard test for coagulation time is the method employing venous blood. Blood is removed from a vein and delivered in a test tube. Coagulation has taken place when the tube can be inverted without displacing the clot. The time will vary with the diameter of the tube. The smaller the diameter of the tube, the more rapid is the clotting time. Either the method of Lee and White or the method of Howell is standard. In the former method, 1 cc. of venous blood is delivered into an 8 mm. diameter test tube previously rinsed with physiologic solution of sodium chloride. The normal coagulation time by this method is eight minutes or less. In the Howell method the syringe is prepared by filling it with a mixture of ether and liquid petrolatum. The mixture is forced out and air is drawn up several times, so that the ether evaporates and leaves a thin coating of oil. From 2 to 4 cc. of venous blood is delivered into a test tube with a 21 mm. bore. Normal by this method is from

ten to twenty minutes. If room temperature is not between 65 to 80 F., the tube should be immersed in water with a constant temperature of 75 F.

BLOOD CULTURE OF STAPHYLOCOCCUS ALBUS

To the Editor:—What line of treatment would you suggest for a patient whose blood culture shows *Staphylococcus albus*? This condition has come on following a mild attack of influenza. Please omit name.

M.D., South Dakota.

ANSWER.—The severity of the infection really determines the treatment. The presence of *Staphylococcus albus* in a blood culture is generally considered a contamination, since *Staphylococcus albus* septicemia, is rather uncommon. When it does occur, it may appear in one of three forms:

1. The mild or transient type, in which few organisms reach the circulation and localize at some point of lowered resistance. A characteristic example of this type is the so-called primary acute osteomyelitis.

2. The severe or pyemic type, associated with symptoms of marked prostration and the development of multiple abscesses.
3. The terminal or fulminating type.

The treatment naturally varies with the severity of the infection. On the whole, it may be divided into systemic or supportive, surgical, and chemical treatment of the blood stream.

Systemic treatment includes such general supportive measures as absolute rest, fresh air, adequate nutrition, forced fluids and careful nursing.

Surgical treatment is frequently necessary, since the disease is one in which the primary focus or the complications consist of inflammatory or suppurative processes. It is essential that the primary focus, if evident, be removed or adequately drained whether it is a boil, a carbuncle or osteomyelitis. The development of secondary or metastatic abscesses must be watched for and these, wherever they occur, should likewise be treated surgically.

The chemical treatment of the blood stream, or what is considered the specific treatment, varies widely, since there actually is no specific treatment.

Excellent results have been obtained following repeated small blood transfusions. Whole blood in amounts of from 150 to 300 cc. is given every other or every third day, a new donor being preferably used each time. Immunized donors have been used with no special influence on the results. Brilliant results also have been reported following the use of vaccine. Mixed vaccines have been used, but autogenous vaccine is preferred. The first dose is 100 million killed organisms given subcutaneously. Injections are repeated at intervals of from three to five days, the dose being increased each time until 1,000 million organisms are given at each injection. Treatment is continued until all evidence of the disease disappears.

In addition, the use of bacteriophage, metaphen, mercurochrome, gentian violet and nuclear extract has been recommended.

DEATH FOLLOWING ANTITYPHOID VACCINATION

To the Editor:—A physician, aged 44, in apparently good health, died about six hours after taking his third prophylactic injection of typhoid vaccine. Shortly after the injection he developed a severe chill and complained of generalized aching, especially in the back. Circumstances seem to indicate a cardiac death. About three or four years previously he refused to take his third typhoid vaccine because of the reaction from the first two. Are there any cases reported of deaths due to typhoid vaccine and, if so, what is the mechanism involved?

JOHN B. BENNETT, M.D., Falfurrias, Texas.

ANSWER.—Death following typhoid vaccination has been recorded in a few instances. Oberndorfer reported a case (Plötzlicher Tod nach Typhusschutzimpfung, *Militärärztl. Ztschr.* 47:286, 1918) in which a man, aged 41, suffering from "nervous sleeplessness," received 0.5 cc. of typhoid vaccine at 2 o'clock in the afternoon and died after eight hours. The symptoms preceding death are not described in detail. The postmortem examination revealed an extensive syphilitic aortitis with narrowing of the coronary openings and involvement of the aortic valves; the heart muscle had small white scars and also fresh hemorrhagic infarcts. The heart was dilated and the lungs, liver and other organs passively congested. According to Oberndorfer, G. B. Gruber has reported that, in a corpulent soldier who died from eight to ten hours after typhoid vaccination, the postmortem examination showed marked hypertrophy and dilatation of the heart, with passive congestion of the organs. Oberndorfer also refers to a case described by Askanazy in a man, aged 22, who died on the fourth day after vaccination; the necropsy showed a severe interstitial myocarditis and radiating scars in the pharynx and the liver. These cases illustrate that in persons with serious heart disease typhoid vaccination, apparently at least, may hasten death.

Russell (Report of Two Deaths from Third Inoculation with Typhoid-Paratyphoid Vaccine, *Kentucky M. J.* 22:378 [Oct.] 1924) has reported two deaths soon after the third injection of typhoid-paratyphoid vaccine. A man, aged 53, apparently in good health, received his third inoculation about 4 o'clock in the afternoon; the patient went home, feeling stiff, achy and cold; he grew worse, became cyanotic, had a chill, and died suddenly. In this case severe reactions, which are not described, followed the first as well as the second inoculation. No cause for death was found on postmortem examination and microscopic examination of the heart muscle and the kidneys. Was this case an example of fatal anaphylactic reaction? The second case is described by Dr. J. M. Shipp in a letter which Russell quotes: "Your case was exactly like mine. My patient was in good health until I gave the third injection. He had no trouble from the first and second doses. Age 19; health good, heart sound: No previous injection of vaccine or serum before the typhoid vaccine. Third injection given at 5 p. m. At 8 p. m. I was called and found him with a temperature of 106, very rapid and bad pulse, looked as though he would die, but about 1 a. m., his temperature went down to 102. He seemed to be better until about 10 a. m., when his fever rose and he died at 1 p. m. He looked like a man that had typhoid fever three or four weeks." Was this a case of fulminant acute infection?

No death is recorded from the typhoid vaccination of approximately 4,000,000 men mobilized in the United States during the World War (Siler, J. F., and Lambie, J. S., Jr.: *The Medical Department of the United States Army in the World War* 9:15, 1928).

SIGNIFICANCE OF CASTS IN URINE OF ECZEMA-TOUS CHILD

To the Editor:—In making a routine urinalysis on a 3½ year old boy who is apparently perfectly healthy (he has a slight eczema of the face and a chronic watery discharge from the nose), I find numerous hyaline and a few granular casts. This specimen was voided in the middle of the morning. A first morning specimen examined four days later contained hyaline casts and probably a slightly larger proportion of granular casts. No albumin was found on either examination. Other tests were normal. What is the significance of this observation? What is the prognosis? What treatment is necessary? Please omit name. M.D., Michigan.

ANSWER:—The occurrence of appreciable numbers of both hyaline and granular casts without albuminuria seems paradoxical. Assuming that there is no error of testing or interpretation, one may content oneself partially with the possibility of hyaline cast formation without nephritis. The granular casts cannot be explained on this basis. A theoretical mechanism of their formation is suggested by the allergic constitution of the child evidenced by the facial eczema and allergic rhinitis. Children with eczema are prone to exhibit urinary abnormalities. Proceeding with theory, one may conceive of the specific allergic lesion as a local renal urticaria affecting a portion of the parenchyma with sufficient disturbance of the tubules to produce casts without giving enough exudate to yield the albumin reaction.

The prognosis should be good in the absence of other changes as reported. Further study and follow up should be made concerning urinalysis, chemical changes in the blood, and blood pressure. Etiologic investigation into the only positive changes found, namely, eczema and allergic rhinitis, should be instituted and specific treatment should be directed along these lines.

PERIODICITY OF MENSTRUAL CYCLE

To the Editor:—A tertipara, aged 30, well nourished, who married at 18, had normal labors and nursed her children, had no miscarriages, and whose menstruation was of the twenty-eight day type and regular, was never sick previous to 1931, at which time she contracted scarlet fever. For the past two years she has menstruated only every three to five months, with normal flow lasting five days. Blood examination reveals 4,500,000 erythrocytes, 5,000 leukocytes and 75 per cent hemoglobin. The urine is normal. The Wassermann reaction is negative. The patient has a gonorrheal infection apparently limited to the cervix, for which she has received treatment, including the use of the electric cauterizer. Smears are now negative for gonococci but a pus discharge continues from the cervix in considerable amount. She has a medium tear of the cervix, which was cauterized. Examination of the pelvic organs reveals no tenderness. The uterus is in normal position. Abnormality of the tubes is not demonstrable. What, if any, treatment will reestablish normal menstruation? Please omit name. M.D., Montana.

ANSWER:—It is extremely difficult and in most instances impossible to change the periodicity of the menstrual cycle. The local pelvic conditions described probably have little or nothing to do with the infrequent occurrence of the uterine bleedings because the latter are controlled by the pituitary gland and the ovaries. The attack of scarlet fever may be a causative factor because the change in the menses followed it. However,

not only will the task of producing a monthly flow be difficult or impossible but there is really no good reason to attempt it. Women who menstruate only two to four times a year, such as the one mentioned, are usually in as good health as those who bleed every month, especially if the duration and amount of the flow are normal. If an attempt is to be made to reestablish a monthly cycle, at least two hormones may have to be administered, hypodermically as an experiment over a long period. For about ten to fourteen days at a time injections of estrogenic substance or theelin will have to be given, and for the next ten to fourteen days, corpus luteum extract will have to be administered. These two hormones are essential because both participate in the control of the changes that take place in the uterine endometrium during the menstrual cycle. In addition it may be necessary to give thyroid preparations by mouth, but the results with these hormones are usually not satisfactory.

ANEMIA AND THROMBOSIS

To the Editor:—I should appreciate your giving me a reference as to the possible effect of anemia on the production of an aortic thrombus. A woman, aged 47, had a hysterectomy, with hemoglobin 45 per cent. She got along well for about a week and then went into profound shock and died with multiple emboli from an aortic thrombus. The patient had been well except for excessive flowing at and between the periods. A hysterectomy was done and a pyosalpinx was removed, at which time the hemoglobin was 45 per cent. There was an uneventful course for about a week, when death followed a profound shock of about twenty-four hours' duration. At autopsy an antemortem thrombus was found to be firmly attached to the upper portion of the thoracic part of the aorta. Multiple infarcts were present in the liver, spleen and kidneys, and the left common iliac artery was plugged by a thrombus. There were no pulmonary infarcts. The lining of the aorta was smooth except for the presence of a few yellow fatty places. On section of the site of the thrombus, no change of the underlying aortic wall was made out. There was no sign of peritoneal inflammation. Please omit name. M.D., California.

ANSWER:—In a case such as described, one would naturally think of a primary thrombus originating in the veins at the site of the operation. However, unless there was a patent foramen ovale, one would expect emboli from this source to lodge in the lungs. No such observations, however, were reported in this case. Infection may be thought of as a possible or probable cause of the thrombosis. Without assuming an operative infection, there was a pyosalpinx which could easily give rise to a bacteremia. It is possible that such infection had occurred and that a thrombus formed on the wall of the aorta with superficial, slight and undiscovered anatomic evidence of its infectious origin.

There is little warrant for speaking of the direct influence of anemia in favoring thrombosis. Yet, when secondary anemia of the chlorotic type was common, thrombosis, of the veins particularly, was not especially rare. In fact, one distinction between chlorosis and pernicious anemia was, as stated in the textbooks, that thrombosis was common in chlorosis, while in pernicious anemia it was quite rare.

HEREDITY IN HARELIP AND CLEFT PALATE

To the Editor:—Oct. 26, 1930, a first child was born. The baby had a harelip and a cleft palate. The youngest brother of the father, nineteen years younger, had had a double harelip and cleft palate. Nowhere else in the family history is there any record of the deformity. Through a series of operations the child's deformity was corrected. However, the surgeon adheres to the theory that such cases are hereditary. Recently, Dr. Royal S. Copeland, in his newspaper series, announced that such troubles result from an injury to the mother when she is carrying the child. Is he correct? The mother is again pregnant. Does the second child have a good chance of escaping such a curse? Please omit name. M.D., Pennsylvania.

ANSWER:—The available statistics would suggest that there is an hereditary predisposition in something like 30 per cent of the occurring cases of congenital face clefts. From the history of many cases has arisen the impression that excessive vomiting by the mother early in pregnancy is an important feature in quite a number of them. In some others the mother has had a serious tooth complication early in pregnancy, and the impression that harelip and cleft palate occur more frequently among the poor than the well-to-do makes one feel that there might be a nutritional basis. Possibly against this it is a recorded observation that harelip and cleft palate seem to be rather common among the lion cubs born in the London zoo, but Arthur Keith has said that no prenatal handling of the mother lionesses has ever been found that seemed to influence this occurrence. According to observation, the intelligence of the average child so afflicted is equal to that of the so-called normal child; what the older observers interpreted as a basic average lower order of intelligence was a misinterpretation of faults and deficiencies dependent on lack of oppor-

tunity. For instance, unless handled properly, a child with a cleft palate is apt to be particularly deaf from the ear complications that so frequently accompany it; the resulting poor speech makes it difficult for the teacher to understand all that the child says in class, and the appearance of a poorly repaired harelip may develop a real inferiority complex. All these are things that can be taken care of, and it has been observed that the extra attention given to these children by intelligent parents and cooperative teachers often makes for finer specimens both in intelligence and in character than might have developed had they not been so afflicted. Outside of giving these children the best surgical care and special training, there is no other suggestion other than to regard it as an "act of God" which must be accepted. The occurrence of two or more children with open clefts in one family is much more rare than the single case.

DIFFERENTIAL DIAGNOSIS OF TOXIC DERMATITIS OR PSORIASIS

To the Editor:—Can urotropin (methenamine), used over a period of years, cause a skin eruption similar to psoriasis? I saw a patient today who had a nephrectomy twelve years ago for pyelonephritis. Since that time she has been taking 30 grains (2 Gm.) of urotropin daily on alternate weeks. Two months ago she developed a skin eruption, which has steadily gotten worse. This eruption is more prominent on the abdomen and the extensor surfaces of the arms and legs. The eruption starts as a small, red papule or bleb. There is intense itching and the lesions are enlarged with the scratch marks. The lesions are distinctly circumscribed, have a red base and are covered with a silver-like scale. There are no lesions on the face or nails or in the hair. Are there recorded in medical literature any cases of psoriasis-like skin lesions caused by the taking of urotropin over a period of years? Kindly omit name.

M.D., Pennsylvania.

ANSWER.—The literature on eruptions due to methenamine (hexamethylenamine) is very limited. There are several reports of dermatitis venenata due to the use of this drug in "accelerators" in the vulcanizing of rubber. One textbook (Andrews, G. C.: *Diseases of the Skin*, Philadelphia, W. B. Saunders Company, 1930, p. 331) says: "Hexamethylenamine may produce localized erythematous lesions or generalized morbilliform eruptions." This is the only reference to dermatitis medicamentosa due to this drug that has been found.

The description given corresponds to a real psoriasis in all but one particular, the statement that the primary lesion is a "small red papule or bleb." This may be a loose use of dermatologic terms, and there are reports of vesicles in early psoriasis; but they are rare and would argue against, rather than for, that diagnosis. Allowing the use of the term bleb to pass as an inaccuracy, the description fits an early psoriasis perfectly. There are no records of such an eruption caused by use of methenamine.

The scaly eruptions due to the arsphenamines and bismuth compounds form patches at first in some cases; but these tend to become confluent and progress to a widespread exfoliative dermatitis.

TENOSYNOVITIS OR TENDOVAGINITIS

To the Editor:—A few days ago a white man, aged 51, an accountant, came to me complaining of swelling in his wrists. About three months ago he noticed small lumps, like shot, under the skin on the back of both hands on the radial side of the wrist joint. He had had no pain in them until about three weeks ago, when he had some aching in them at the time that he had the grip. The aching then disappeared but started to reappear about two weeks ago. The aching has been gradually getting worse and he has noticed that the swellings have been getting larger. The aching runs up the arm along the radius to the midforearm and down the hand to the knuckle of the first and second fingers. For the past two days the dorsum of the hands has been swollen. There is no history of injury or occupational disease. The past history does not lend any aid in the diagnosis nor does the general physical examination, urinalysis, blood counts or Wassermann and Kahn tests. On examination the two wrists appear to be symmetrical, the tumors and swelling appearing alike in the two extremities. There is no discoloration. There are four or five small tumors below the skin at the end of the radius dorsally; they have the appearance somewhat of varicose veins but they are not compressible. They feel like cysts or ganglions, being soft and movable. I surmise that they are synovial cysts of the wrist but because they are bilateral I wondered whether this condition might not be characteristic of some particular syndrome or disease. Please inform me if such is the case and also advise me of the supposed cause and the treatment.

WILLIAM BLOUNT TURNER, M.D., Wooster, Ohio.

ANSWER.—It is probable that this patient is suffering from one of two conditions, either a tuberculous tenosynovitis of the extensor tendons and their sheaths or a stenosing tendovaginitis at the radial styloid process. The description does not state whether the tumors that are felt follow the line of the abductor pollicis longus or whether they are more irregularly distributed over the hand, and for that reason it is

difficult to make an exact statement with reference to the diagnosis.

Tuberculous tenosynovitis is not uncommon at this location and may be bilateral. It has been well described by Kanavel (*Surg., Gynec. & Obst.* 37:635 [Nov.] 1923). Treatment of the condition, as Kanavel emphasized, is careful and accurate dissection and excision of the involved tendon sheaths, with removal of the visceral as well as the parietal layers; in other words, of the synovial covering of the tendon as well as the synovial lining of the fibrous sheath. If such an operation is carefully performed and the wound accurately closed after complete excision there is every reason to hope for prompt healing and freedom from recurrence.

Stenosing tendovaginitis was first described by de Quervain. There is an excellent paper on the subject by Harry Finkelstein (*J. Bone & Joint Surg.* 12:509 [July] 1930). In this condition a thickening and narrowing of the synovial sheath takes place, probably as the result of repeated trauma, possibly complicated by the presence of a low grade infection. The marked pain and tenderness over the abductor longus and extensor brevis pollicis are exaggerated by holding the flexed thumb under the flexed fingers and drawing the closed hand into ulnar adduction. The treatment of this condition is incision of the dorsal carpal ligament over the involved tendons. This incision opens the constricted tunnel through which the tendons glide and permits them to move back and forth without pain.

TREATMENT OF CHRONIC CONSTIPATION

To the Editor:—I have a patient, a man aged 49, who has been troubled with constipation for probably twenty years. He is in apparently excellent health otherwise. At one time he took some kind of laxative, pill or tablet, at least every other night. For the past five years, however, no drugs have been taken, fairly satisfactory bowel movements being obtained by taking daily one tablespoonful of liquid petrolatum with agar and from two to four teaspoonfuls of psyllium seed. During the past few months the bowel movements have not been so good. Occasionally the patient has a slight headache, a bad taste in the mouth, coated tongue and ribbon stools. He does not appear to be neurotic. There is no gastric disturbance, no mucus, no pain, and but little tenderness. Roentgen examination shows a spastic colitis. The patient is an office worker, though he does quite a little outdoor walking. Is it harmful to use psyllium seed over so long a period? Roughage is contraindicated in spastic colitis, yet without the roughage (or drugs) there will be no bowel movement. What treatment should I recommend? Please omit name.

M.D., Chicago.

ANSWER.—Roughage is contraindicated only when the colon is actually in a spastic condition. On the other hand, it is a preventive of "spastic colitis" when used in intervals between attacks. During an attack of spasm, a smooth diet should be used, with sufficient liquid petrolatum to render the bowel movements soft. When the attack has passed, it is desirable to add roughage to the diet—not only psyllium seed but also fruits and vegetables. The most tender forms of these are added first; and, if these are well borne, the coarser vegetables are added up to the point of tolerance, which in any case can be determined only by experience. If such a patient can eat a fairly coarse diet, he is likely to be quite free from any tendency to relapse. If the intestine is handicapped by some anatomic abnormality, it may not be possible to push the roughage beyond a certain point. Such a patient may need to be helped along by bran, psyllium or liquid petrolatum, used more or less indefinitely.

EFFECTS OF ANESTHESIA ON KAHN AND WASSERMANN TESTS

To the Editor:—How long after ether anesthesia do the Kahn and Wassermann tests on the blood give false positive reactions? Do ethylene and other gas anesthetics give false positives? If so, for how long a period? Does any other form of anesthesia give false reactions with the Kahn and Wassermann tests for syphilis? Kindly omit name.

M.D., Joliet, Ill.

ANSWER.—The concept that a person, when under anesthesia, may give false positive serologic reactions for syphilis is an old one. It is generally believed that anesthesia increases the anti-complementary properties of the blood, which in turn requires special care in the performance of the Wassermann test to avoid false positive reports. The Kahn test, not being influenced by anti-complementary properties of serum, is still less affected by anesthesia. There is no conclusive experimental evidence for the assumption that either test gives false positive reactions during anesthesia. Nevertheless, as a factor of safety, no serologic reaction obtained during anesthesia should be depended on, particularly if not supported by clinical observations. At least forty-eight hours should elapse between a general anesthetic and the drawing of blood for a serologic test.

POSSIBLE TRAUMATIC SUBDURAL HEMORRHAGE

To the Editor:—A 4 year old girl, apparently in good health up to two weeks before, was seen, March 29, complaining of frontal headache and vomiting (not projectile). The temperature was normal, the pulse rate 90. When seen, March 30, at 10 a. m., headache persisted, as did the vomiting; the temperature and the pulse rate were the same, but the child appeared more apathetic and drowsy. The face was quite flushed. The pupils were equal and regular; they reacted to light and in accommodation, but sluggishly to the former. There was a positive *tache cérébrale*; the knee reflex was absent; the Babinski reflex was negative. The child was yawning about every ten minutes. At 3 o'clock the same day the child had lapsed into a deep coma, from which she could not be aroused. The temperature now was 102 (rectal). The right pupil was dilated, the left was contracted, and both were fixed. There were convulsive seizures involving the right arm and leg at intervals of half an hour followed by a position of tetany (opisthotonos, fingers clinched with thumb drawn under, and jaw fixed), which was maintained for three or four minutes. Lumbar puncture was done at 6:30 p. m. and 15 cc. of clear fluid under increased pressure withdrawn. It was negative for organisms on smear and culture; there were many red blood cells; the cell count was 20. The temperature now was 105. At 7:30 p. m. the child died. On going more deeply into the history I learned that three weeks before the child had been "grazed" by a truck and knocked down in the street and carried home to her mother, who found no evidence of any injury. The child was severely reprimanded and spanked. From then on the child showed a progressive loss of interest in her dolls, her playmates and everything in general, together with an increasing nervousness. About one week later the child began to cry out in her sleep and also grind her teeth while sleeping. This hydrocephalic cry was more noticeable as the headache made its appearance. These are all the data available. What diagnosis would you suggest? Please omit name.

M.D., New Jersey.

ANSWER:—In most states this would have been a coroner's case and the coroner would probably have ordered a necropsy. Even if the child apparently was not seriously injured at the time that she was knocked down by the truck she may well have had a slowly developing subdural hematoma. It is, of course, possible that she had tuberculous meningitis and that the injury was a coincidence. However, if the cell count was only 20 it is not likely that any kind of meningitis was responsible for such severe symptoms. In the absence of a necropsy one must, of course, admit other possibilities, such as a brain tumor which had not previously caused symptoms. Since nothing is said about the eyegrounds, it is assumed that choked disk was not present. With the data given, the diagnosis favors traumatic subdural hemorrhage.

DIFFERENTIAL DIAGNOSIS BETWEEN ANTEMORTEM AND POSTMORTEM THROMBI

To the Editor:—I am exceedingly anxious to learn by what scientific laboratory tests the differential diagnosis can be made between an antemortem and a postmortem blood clot and whether or not the examination of a postmortem blood clot, made immediately after death, can be distinguished from a blood clot found in a body dead at least twelve or more hours? Can it be determined by the postmortem examination that a body had been alive at the time that it is alleged to have come to its death by falling or being thrown from a great height as against the claim that the body came to its death, several hours before, by falling or being thrown against a stone wall and suffering a compound fracture of the skull? It has been claimed by pathologists that they are able to determine that the body was alive when it was thrown from the height in question, by reason of the fact that they found blood in certain organs. How can this proof be sustained in court? If you are unable to give me this information will you kindly mention certain authors whom I might consult? I will be pleased to reimburse you for any reasonable expense attached to your investigation or answer to these questions. Thank you very kindly for the courtesy of a prompt reply. Please omit name.

M.D., Illinois.

ANSWER:—In answer to the first part of the first question it may be said that, generally speaking, an antemortem clot—thrombus—is firmly adherent at some point or points of the vessel or the heart cavity within which it has been formed. It may vary in appearance and consistency according to age and other circumstances. If formed shortly before death by extension from an older thrombus it may be largely fibrinous and somewhat elastic, and if it is in the heart there may be marks to show that it has been subjected to the heart's action. After death the blood tends to settle in dependent parts; in the heart and the large veins the red cells will be at the bottom, and the clot above may be more or less yellowish. These layers may possibly give some indication of the position of the body when the blood clotted. Postmortem clots are not adherent to the wall of the vessel or heart cavity with which they are in contact.

The second part of the question does not seem quite clear. It appears to refer to the possibility of distinguishing between blood clots found immediately after death and later. To distinguish a postmortem clot found immediately after death from one found in a body dead for, say, twelve hours is not possible.

In answer to the second question it may be said that, if the body has been dead several hours before its precipitation from

the height, immediate examination might reveal unmistakable signs of earlier death, such as more or less well developed postmortem rigidity, postmortem lividity, and possibly even beginning decomposition.

The third question is not definite enough to warrant further consideration than to say that blood may be found in various organs and places in deaths from various causes and under various circumstances.

PROTECTION OF EAR AGAINST EXPLOSIVE NOISES

To the Editor:—Please give me information regarding the best method of protecting the ears when engaged in target practice with small arms, such as pistols, revolvers and rifles. There are on the market several "ear plugs" for this purpose. Which do you consider to be the most proficient? Is the use of cotton sufficient for this purpose? If so, should it be dry or moistened with glycerin or some other substance? Target practice is the chief source of recreation of this patient, and the continued ringing in the ears for the past three days has been diagnosed by an otologist as due to nerve disturbance from this cause. Please omit name.

M.D., California.

ANSWER:—While many appliances have been devised to use as ear plugs to prevent damage to the drum membranes in the presence of rifle or cannon shot, the use of a cotton pledget moistened with glycerin has been found to be about as good as anything. If very loud sounding guns are used, it is sometimes better to open the mouth at the time of the discharge of the cannon. It is quite possible that producing intense noises near the ears will cause a degeneration of a certain portion of the organ of Corti and the auditory nerve itself, thus giving rise to a distressing tinnitus.

WIDAL TESTS AND EXAMINATIONS OF FOOD HANDLERS

To the Editor:—The city health department of San Diego, Calif., requires an examination of food handlers. The only laboratory work required is a specimen of blood for Wassermann and Widal tests, and a mouth smear for Vincent's. This, in my opinion, is insufficient; most certainly this work should cover, if it is to be comprehensive, sputums for tuberculosis and possibly throat cultures for diphtheria. Please tell me specifically whether or not the Widal test is of any value in this connection except in possible occasional value in picking up an individual who is coming down with typhoid. In my opinion, a large portion of Widal tests are positive because of former attacks of typhoid or inoculations against typhoid, which have been given in such widespread amount, especially to ex-service men. Is the Widal test of any value in this condition? Please omit name.

M.D., California.

ANSWER:—A Widal test used in the examination of food handlers, except for a possible laboratory diagnosis of typhoid and paratyphoid fever, is of little or no value. The fact that a person shows a positive Widal test and has no clinical evidence of typhoid or paratyphoid fever shows that he probably has received typhoid immunization or has previously had an attack of the disease.

The proper method to use to detect typhoid carriers is to examine specimens of feces and urine, preferably collected after elaterin catharsis. This method should be used also in detecting carriers of paratyphoid fever, and bacillary and amebic dysentery.

Some cities require a physical examination of food handlers, and suggestive chest observations are followed up by a careful physical and sputum examination.

OPTIMUM TIME FOR BLOOD TRANSFUSION

To the Editor:—I should like information concerning the time when a transfusion of blood serves its greatest value to the recipient. In the case of an operation of election, I want to know whether the transfusion should be done immediately or twelve, twenty-four or forty-eight hours before the operation. I have in mind a patient with tuberculosis of the spine who is to be subjected to a long operation of the Hibbs, Albee or the combined types; another who should have an arthroplasty of the hip; another who should have a laminectomy for a suspected spinal cord tumor. As a prophylactic measure a blood transfusion is advisable. Should it be done twelve, twenty-four or forty-eight hours before the spine operation? In short, I want to know when the recipient derives maximum preoperative benefit from a blood transfusion. Please omit name.

M.D., Illinois.

ANSWER:—Transfusions are given preliminary to extensive operations such as are mentioned usually as a prophylactic against shock. In addition they will of course raise the hemoglobin and red cell count, improve the patient's general condition and make the patient a more favorable operative risk. There has been some difference of opinion as to the ideal time to employ this procedure, but experience has shown that the greatest benefit is derived when the transfusion is given immediately prior to the operation. As soon as the transfusion is completed, the anesthesia is begun. Patients treated in this fashion usually show no evidence of shock. Large doses of

blood should be employed: for adults, between 750 and 1,000 cc. For extremely extensive and shocking procedures it is occasionally necessary to repeat the transfusion after the operation.

MONILETHRIX

To the Editor.—A child, aged 3 years, has a disorder of the scalp. The hairs are scanty, coarse and brittle. There are also small papular elevations in the scalp. A diagnosis of monilethrix has been made at a skin clinic. What are some therapeutic measures known for this condition? Please omit name. M.D., St. Louis.

ANSWER.—Monilethrix is familial and probably an hereditary anomaly like ichthyosis. No effective treatment is known. Epilation by roentgen rays has been reported of benefit in some cases, without causing any improvement in others. Stimulation by means of ointments containing salicylic acid, resorcinol monoacetate, sulphur and one of the tars may be tried. A cautious trial of thyroid or anterior pituitary extract or a combination of them might be made. A good article on this subject is that by G. M. MacKee and Isadore Rosen (*J. Cutan. Dis.* 34:444 [June], 506 [July] 1916).

AUSCULTATION IN EMPYEMA

To the Editor.—1. What is one to note on auscultation in empyema with an underlying pneumonic condition of the lung? 2. In pleurisy with effusion without a pneumonic process? 3. In empyema without a pneumonic process? In all three cases, granted that the bronchi are not plugged with tenacious mucus, and breath sounds are transmitted to the pneumonic process. GERALD A. CYR, M.D., Waterville, Maine.

ANSWER.—1. The layer of pus usually obscures or obliterates the breath sounds and muffles voice sounds; but, in places where the pus layer is thin, bronchophony may be present.

2. Breathing is faint or absent. Voice sounds frequently are nasal-egophony.

3. The breath is usually inaudible. The voice sounds are faint or nasal. The whispered voice is better transmitted through serous than through purulent exudate.

PERSISTENT PAIN AFTER HERPES ZOSTER

To the Editor.—A woman, aged about 50, had an attack of herpes zoster along the course of the lumbo-abdominal nerves, eighteen months ago. The eruption disappeared in the usual time but the severe pain still persists. Has there been any treatment discovered that will relieve these pains other than severing the posterior nerve roots at the spine? Please omit name. M.D., Texas.

ANSWER.—Paravertebral injection of a local anesthetic and, if this is but temporarily successful, paravertebral injection of alcohol might render the operative procedure unnecessary.

ELECTROCARDIOGRAPHIC APPARATUS

To the Editor.—Is there a practicable portable electrocardiograph on the market? Is the Sanborn machine accurate and sufficiently rugged for practical use? JAMES L. ROBINSON, M.D., Los Angeles.

ANSWER.—Portable electrocardiographs are of the amplifier or the string galvanometer type. Several practicable machines of both types are now available. The Victor (amplifier) and the Sanborn (string galvanometer) are among the most satisfactory instruments. Each, arranged in convenient carrying cases (the Victor in two, the Sanborn in three), is equipped with battery and charger and will operate anywhere; the total weight is about 100 pounds. These are more satisfactory for portable work than the electrical models. The advantages and disadvantages of these types of electrocardiographs are discussed in "The Fundamentals of Electrocardiographic Interpretation," by J. Bailey Carter (*THE JOURNAL*, Oct. 1, 1932, p. 1167).

RETENTION OF URINE IN DEMENTIA PARALYTICA

To the Editor.—A man with dementia paralytica in the advanced stage suffers from retention of urine. The bladder is distended up to the umbilicus. Conservative measures, such as hot applications to the bladder region and continuous baths, failed to provoke spontaneous urination. Should the patient be catheterized? One of my colleagues states that the urologist Hugh H. Young expressed an opinion that patients with dementia paralytica with retention of urine should never be catheterized, because of danger of infection (cystitis?), and also because their bladders do not rupture. Should the patient be left alone or catheterized? Please omit name. M.D., Pennsylvania.

ANSWER.—A patient with retention from a cord bladder may be allowed to run along until the bladder overflows. This may decrease the chances of infection but may increase the possibility of renal damage due to back pressure.

In many of these patients, sooner or later, infection develops even though they are not catheterized. The use of an indwelling catheter, left in place for some weeks, may improve the bladder function to some extent. However, the prognosis in these cases is bad as far as function of urination is concerned.

BLOODY SEMEN

To the Editor.—A man of 70, who had a suprapubic (central lobe) prostatectomy performed five years ago with a histologic report of adenoma, now for the past year and a half has ejaculated bloody or chocolate colored semen at intercourse. What is the probable cause of this? Please omit name. M.D., Minnesota.

ANSWER.—It is not likely that the prostatectomy of five years ago has anything to do with the present bloody ejaculations. The posterior urethra should be examined with a cystourethroscope. Often distinct pathologic conditions, such as tumors, either benign or malignant, or areas of granulation or ulceration, may be found. Of lesser frequency may be mentioned small pieces of calculi broken off from a bladder calculus, which may be lodged in the urethra. At times the blood may be due to a seminal vesiculitis.

"USE OF THYROID"

To the Editor.—I was much interested in the question put to you by a physician from North Carolina, which under the title "Use of Thyroid" appeared on page 1797 of *THE JOURNAL*, June 3, and in your reply. The question I thought thoroughly pertinent. With your reply I cannot entirely agree. If you care to present my views to the doctor through your columns, I shall be glad to have you do so.

In the first place, I think it fair to assume that the doctor means that the dose of thyroid mentioned was per day, not per week. The important point about dosage you have not raised; namely, What brand of thyroid was used? The different brands vary greatly in strength. In calorogenic activity, for example, I have found that 1 grain of Armour's preparation is equivalent to about 3 grains of Burroughs Wellcome's or to two-thirds grain of Parke Davis's. So unless the brand is known, dosage is meaningless.

I would take issue with your advice that intravenous thyroxine be substituted. I do not believe that thyroxine intravenously, or any other way, has any place in the treatment of hypothyroidism. If thyroid is really needed, thyroid by mouth will work. However, I am far from convinced that the doctor's patient needs thyroid at all. There are not a few normal people or people without thyroid disease whose basal metabolic rates run as low as -22. Indeed, I practically never see the full-blown picture of myxedema except when the basal metabolic rate level is well below -30. The present patient may well be one whose low metabolism is not caused by any thyroid lack. Thyroid therapy therefore may be simply making her slightly thyrotoxic. A feeling of well being is often a manifestation of thyroid excess. Though loss of appetite isn't the usual finding, it nevertheless occurs in some thyrotoxic persons. The doctor doesn't tell what happened to the metabolic rate when thyroid was given. This it is important to know as well as the true dosage. Presumably it rose. Why the heart rate didn't rise I cannot say. Perhaps she has heart block and it cannot go up. We have observed one such case in the Thyroid Clinic of the Massachusetts General Hospital (Aub, J. C., and Stern, N. S.: *Thyroid Extract and Heart Block*, *Arch. Int. Med.* 21:130 [Jan.] 1918). An electrocardiogram would throw light on this. It would also show whether the T wave changes characteristic of myxedema are present. Another laboratory finding which may be helpful in distinguishing between genuine hypothyroidism and other forms of hypometabolism is the blood cholesterol. Dr. L. M. Hurxthal has found elevations of over 250 mg. per hundred cubic centimeters in true hypothyroidism, and normal levels not over 200 mg. per hundred cubic centimeters in non-myxedematous low rate cases. His remarks will appear in the *New England Journal of Medicine* in the discussion of the symposium on endocrinology of the Section on Medicine of the Massachusetts Medical Society held June 6.

My recommendation in the present case would be that, for the time being at least, thyroid be discontinued and some cause for the symptoms, other than hypothyroidism, be sought.

J. H. MEANS, M.D.,
Massachusetts General Hospital, Boston.

AFRICAN TRIBES WHICH LIVE ON BLOOD

To the Editor.—In *THE JOURNAL*, April 15, Dr. Halton inquires about an African tribe which lives on blood. The Masai probably were meant. If the inquirer will get a copy of "The Physique and Health of Two African Tribes," by Gilks and Orr, Medical Research Council Special Report Series 155, he will find all the dietary information he desires.

"The staple articles of diet are meat, milk and blood. The blood is drawn from the living animal by puncture of the jugular vein with an arrow."

"The average diet of Masai males of the warrior class is: meat, 1,135 Gm.; milk, 2,000 cc.; blood, 50 cc."

A neighboring tribe—the Kikuyu—live on an almost exclusive vegetarian diet of "cereals, tubers, plantains, legumes and green leaves." The commonest diseases found among the Kikuyu were bronchitis and ulcers, among the Masai intestinal stasis and arthritis.

Quotations are from the mentioned report, which may be purchased from His Majesty's Stationery Office, London, for 2 shillings.

B. B. MICHENER, M.D.,
Friends Mission Hospital, Kisumu, Kenya.

Italian renaissance, and of its progress in the seventeenth, eighteenth, nineteenth and twentieth centuries. There is steady stress on the clinical tendency of Italian medicine as contrasted with the theoretical and laboratory trends of northern Europe. Among the numerous distinguished Italian physicians of whom thumb-nail sketches are given, a few may be selected for special mention: Vesalius (1514-1564), who showed that Galen's observations were based exclusively on the cadavers of animals; Fracastoro, who wrote the famous poem "Syphilis, sive morbus gallicus" (1530); Malpighi (1628-1694), the first great medical scientist who used the microscope in his studies; Morgagni (1682-1771), founder of modern pathologic anatomy; Spallanzani (1729-1799), who discovered the possibility of generation by division; Flaiani (1741-1808), who contributed largely to the discovery of exophthalmic goiter; Bassi (born in 1773), a pioneer in micropathology; Cesare Lombroso (1839-1909), famous for his studies in psychiatry and the founder of Italian anthropologic studies, and Guido Baccelli (1832-1916), pathologist, teacher and humanist.

Der Coronarkreislauf: Physiologie, Pathologie, Therapie. Von Dr. Max Hochrein, Professor an der Universität Leipzig. Paper. Price, 24 marks. Pp. 227, with 54 illustrations. Berlin: Julius Springer, 1932.

In this book the author has supplemented a great volume of clinical and experimental work in the Leipzig clinic with a carefully prepared outline of the literature dealing with coronary circulation. The first section, devoted to the consideration of anatomy, is divided into discussion of the coronary arteries, coronary veins and lymph circulation. Under this heading is also considered the mechanism of nervous control. These subjects are exhaustively covered. The second section is devoted to a presentation and discussion of experimental research on the coronary. This section contains the greatest amount of original work of the author. In this division the author reports the experimental and clinical work in physiology and pharmacology of the circulation. Great importance is attached to this because of the close relationship between the circulation of blood itself through the heart and the heart action. The third section is devoted to the discussion of the coronary system itself and the discussion is taken up under the headings of pathologic physiology and pathologic anatomy, with the final part devoted to the clinical aspects of coronary disease. To the clinician, the final section is of greatest interest. The fund of material is well displayed in the representative cases cited. This material is presented by a discussion of the special disease conditions, which includes a study of general symptomatology and electrocardiography in coronary disease. The book is closed with a discussion of special therapy in the conditions discussed. The work is complete and well written. The bibliography is especially complete. While there is little new material in this book, the great care with which the material has been collected and presented makes this a noteworthy book on coronary disease.

A Manual of Embryology: The Development of the Human Body. By J. Ernest Frazer, F.R.C.S., Professor of Anatomy in the University of London. Cloth. Price, \$3. Pp. 486, with 282 illustrations. Baltimore: William Wood & Company, 1932.

This "manual" has three characteristics: 1. It is written for students by an examiner and teacher who invites his students to look at embryos instead of at pictures or descriptions. 2. It is condensed. It is not a complete review and storehouse of information but an introduction helping the young students to form intelligent and connected mental pictures of the developing embryo. 3. Regions of the body are presented instead of structures or systems of structures. This method is followed partly because it is believed to be more convenient and useful to the student and partly because the study is based on the author's preparations. The first section (110 pages) is devoted to early and general development of the embryonic period (first two months), followed by a chapter on general growth throughout intra-uterine life and another on maternal connections—placenta, fetal membranes and parturition. This part is more condensed than in most textbooks. The second part (364 pages), is devoted to the development of regions—and organs and systems. (It is impracticable to follow the regional method exclusively.) The illustrations are nearly all original pen and ink sketches or diagrams made by the author. A valuable feature is the

representation of a structure at several successive stages of its development with numbers appended to each part representing the length of the embryo in millimeters. The manual on the whole represents an attempt at simplification and can be recommended for the use of medical students in the general or basic medical course. Students with special interests will want to refer also to larger textbooks.

Recent Social Trends in the United States. Report of the President's Research Committee on Social Trends. In two volumes. With a foreword by Herbert Hoover, President of the United States. Paper. Price, \$10. Pp. 1568, with illustrations. New York & London: McGraw-Hill Book Company, 1933.

This is a great symposium of views by leading authorities as to the trend of various interests in this country during the last twenty-five years. The essays and sketches are exceedingly uneven in their content and presentation. Particularly unfortunate was the choice of Harry H. Moore, director of the work of the Committee on the Costs of Medical Care, to prepare the section on medicine. Mr. Moore was long since committed to a certain definite point of view which has not changed, and his contribution to this series merely serves to emphasize further his personal bias for state medicine. It is true that there has been a trend toward state medicine, but it might be well in connection with the discussion of this trend to point out that the vast majority of the American medical profession is opposed to the trend and that nothing is inevitable in the field of social changes. The two great volumes composing this symposium offer a vast amount of statistical material and data, so that they constitute an invaluable reference work for every one interested in discussions in this field.

Set the Children Free! By Fritz Wittels. Translated by Eden and Cedar Paul from the fourth German edition. Cloth. Price, \$2.75. Pp. 242. New York: W. W. Norton & Company, Inc., 1933.

This is an English translation of the fourth original German edition, which was revised by the author for this purpose. The manner of presentation and point of view of the author are familiar to many in this country, as he lectured extensively throughout the United States and is also known through his writing on psychoanalytic problems. This is intended as a textbook for parents of normal children and to be used as a guide in the psychologic care of children from a psychoanalytic standpoint. The author attempts to present the mental life of the child and the laws under which he functions; also the manifold problems of childhood and how the parents can help the child to meet them. However one may feel as to the correctness of the author's views, one cannot help but appreciate that Dr. Wittels has a sympathetic understanding of most of the practical problems of children. The text covers the usual list of subjects discussed in works on child training as well as problems relating to stepchildren, illegitimate children, orphans, and children of divorced parents. The last chapter is a brief account of the educational system of Germany and Austria and the recent changes it has undergone and the suggested changes for the future. As in most books on this subject, the reader must not be carried away by what appears to be logical. A judicious parent reading this book must examine carefully the evidence presented. With the author leading the children in conquest for freedom, he must weigh the facts. The work is stimulating and will materially assist the reader to appreciate the mutual problems of parenthood and childhood.

Die Röntgendiagnostik der männlichen Harnröhre. Von Dr. Erich Langer, dirigierenden Arzi der dermatologischen Abteilung am Krankenhaus Berlin-Britz. Paper. Price, 9 marks. Pp. 92, with 60 illustrations. Leipzig: Leopold Voss, 1931.

This small book demonstrates in a brilliant manner the pathologic changes in the male urethra which can be visualized by roentgenography. These changes are often in the nature of a surprise. No other method will show with the same clarity the extent and relations of strictures, para-urethral canals and congenital anomalies. The technic of roentgenography of the male urethra is not simple, but it has been admirably mastered and described by the author. The illustrations are exceptionally clear and each carries a legend in French, German and English. The volume can be heartily recommended and will well repay careful study of its contents.

Review of Legal Education in the United States and Canada for the Year 1932. By Alfred Z. Reed, Staff Member in Charge of the Study of Legal Education. Paper. Pp. 67. New York: Carnegie Foundation for the Advancement of Teaching, 1933.

"Balancing the budget" is a sufficiently familiar phrase. In the Annual Review of Legal Education, however, Dr. Reed makes use of it in an unaccustomed sense, for he applies it not merely to the fiscal operations of law schools and universities but to the broader aspects of the problem of legal education regarded from the point of view of society as a whole. He asks what proportion of the cost of his education should be met by the student himself and what part by the voluntary or involuntary contributions of others. Should public funds be devoted to vocational and professional education irrespective of the number of specialized experts that our current economic system can absorb?

The author discusses at length the problem of student selection, declaring that the simplest, most infallible method of determining whether an individual is qualified to practice a profession is to let him try, and acknowledging that no system of selection can ever be devised so scientifically accurate that it will leave in the profession every one who ought to be there and eliminate every one who ought not. He gives two reasons for rejecting the policy of "laissez faire." First, because of its unfairness to the public, whose interests would often be inadequately served, and, second, because of its cruelty to the individual, who may discover his error only after a great waste of time and money and when it has become almost impossible for him to prepare himself for another career. Granted that authority may intervene to bar the path to a chosen vocation, the later in a candidate's preparation that this barrier is erected the less likely it is to be an efficient protection to society; the earlier, the less injurious to the applicant himself, for he may the more readily adapt himself to another objective.

The effect of the depression on law school attendance is shown by a decrease of 15 per cent from 1928 to 1931. Figures for 1932 are still lower.

Comparative tables show the present requirements for admission to the bars of sixty states and Canadian provinces, and changes in the number of law schools of different types, and of their students, during the last forty years.

In the United States and Canada, 88 schools are classified as full time, while 107 are part time, offering instruction at hours convenient for self-supporting students. Current standards of the American Bar Association and of the Association of American Law Schools are found in an appendix.

The Review of Legal Education is distributed without charge by the Carnegie Foundation, 522 Fifth Avenue, New York.

Le virus tuberculeux. Par le Dr. Jean Vaitls, professeur de pathologie à l'Université d'Athènes. Bibliothèque de pathologie sous la direction de Léon Bernard, professeur de clinique de la tuberculose à la Faculté de médecine de Paris. Préface du Dr. Calmette. Paper. Price, 36 francs. Pp. 241. Paris: Masson & Cie, 1932.

This manual is a partisan exposition of the views of the Pasteur Institute group on the bacteriology and immunology of tuberculosis. The first chapter deals mainly with various normal and abnormal forms of the tubercle bacillus, with special emphasis on granular and non-acid fast forms. The second chapter is devoted to the description of filtrable forms, and methods are given for successful filtration. An interesting point is the statement that BCG cultures have only a few filtrable elements. The author gives detailed experimental filtrations, out of which typical bacilli and virulence were obtained by animal passage. The third chapter is devoted to heredity and maternal transmission. The author dispenses the ideas of hereditary resistance and hypersensitiveness but states that a mother with advanced progressive tuberculosis may pass the virus to the fetus more often than usually thought, the lesions in the infant differing from those due to virulent bacilli. The last chapter is on antituberculous vaccination with the "bacillus bilie de Calmette-Guérin" (BCG). The discussion of technical methods is cursory, and most of the text is given to quotations of certain experimental results and their confirmation, and a refutation of contradictory work. In this book, as in other writings from the same source, any contrary results are imputed to ignorance and error. The statistics presented do not vary in any way from those previously published

by the originator of this method of vaccination, and those interested can find them in recent English publications. The final and all important thesis of the book—that prophylaxis in tuberculosis is to be gained by the use of living, attenuated, nonpathogenic organism of fixed virulence, to be used as a vaccine—is reached by means of the views exposed gradually throughout the book. The author is convinced of the existence of granular and filtrable forms of the tubercle bacillus but does not credit the American dissociation forms; he believes, in spite of a return to virulence of many cultures by animal passage, and the transfer of a virus from mother to child in utero, that BCG is an organism of fixed virulence, all experimental work to the contrary notwithstanding. It is therefore the answer to the long search for a suitable prophylactic method. The story is a good, one-sided view which almost reaches the point of propaganda.

Chemistry of the Opium Alkaloids. By Lyndon F. Small, Consultant in Alkaloid Chemistry, United States Public Health Service, University of Virginia. Assisted by Robert E. Lutz, Associate Professor of Chemistry, University of Virginia. Prepared by direction of the Surgeon General. Supplement No. 103 to the Public Health Reports. U. S. Treasury Department, Public Health Service. Cloth. Pp. 375. Washington, D. C.: Supt. of Doc., Government Printing Office, 1932.

As the title indicates, this is a book on pure chemistry. There is no suggestion of pharmacology or therapeutics. The material has been assembled in the course of a systematic study of the literature of the opium alkaloids and gives the impression of completeness and accuracy. The nomenclature adopted is that most commonly used in contemporary publications; in case of doubt, the German name has been accepted. This, as the authors state, leads to some unavoidable inconsistencies, but one has no difficulty in finding a discussion of the substance desired. This is a valuable source book of references on alkaloid chemistry, but especially the chemistry of opium. The authors have included a list of books on alkaloid and synthetic chemistry seldom cited in bibliographies, which in itself is of great value to chemists, research workers and others interested in chemical literature. The book is divided into two parts: 1. The benzylisoquinoline and minor alkaloids, which includes the chemistry of papaverine, xanthine, laudanose, laudanine, laudanidine, codamine, tritropine, narcotine, gotarine, tarconine, gnoscopine, oxynarcotine, narceine, hydrocotarine, cryptopine, protopine, papaveramine, lanthopine, meconidine, rhoeadine and aporeine. 2. The phenanthrene alkaloids, which includes morphine, pseudomorphine, codeine, neopine, porphyroxine, the halogenomorphides and halogenocodides; the isomers of morphine and codeine, the thiocodides, the desoxycodones, codeinone, hydroxycodeinone, apomorphine, the methylmorphimethines, morphol and morphenol, thebaine, thebainone, thebenine, morphothebaine, phenyldihydrothebaine, and the constitution of morphine. The references are exhaustive and include 1,976 or more. It is quite impossible to appreciate the vast amount of work necessary to complete a work of this kind, or to evaluate it too highly. It is a book that should be in every chemical, pharmacologic and pharmaceutical library and is recommended to every one interested in the subject.

Grundzüge einer Konstitutionsanatomie. Von Professor Dr. Walter Brandt, Abteilungsvorsteher am Anatomischen Institut der Universität Köln. Paper. Price, 28 marks. Pp. 382, with 135 illustrations. Berlin: Julius Springer, 1931.

Professor Brandt is concerned not with diathesis or predispositions of human bodies to disease but with the dynamic constitution of living organisms. It is not a medical treatise based on human anatomy and its variations but a contribution to fundamental biologic philosophy. The phenomena that make up the life history of a living organism, plant or animal represent the play of energies through structural forms in a series of processes, which constitute its life history. These processes follow a regular sequence, each completing itself and giving place to others. They fall into three categories: (1) embryologic formation, (2) growth and (3) differentiation. Through them, all the various "types," genera and species of animals and plants arise, live through their life changes and die. Professor Brandt seeks to understand the causes underlying, producing and governing these phenomena. Obviously there is involved a space factor—form or "orthotopic potential"; and also a time factor—speed of determination; i. e., rate at which

stage follows stage in the life history or metamorphosis. The laws of embryologic formation are revealed in the whole science of experimental embryology (see Brandt's law of specific induction, 1927). Growth is influenced by the environment, external and internal (hormones). The conditions of growth and differentiation are discussed and illustrated by citation of results of experiments on the development of many plants and animals. The author suggests that the familiar systematic classifications based on the forms of adults be supplemented by another based on something more dynamic; namely, reactions to experimental embryologic procedures. In this, "isodromes" or "determinative equivalents" would be classed together. Through experimental embryology he hopes to arrive at experimentally provable relationships, which will add much to classification from the standpoint both of types and of heredity. The book is the product of many years of study and independent thought on fundamental biologic problems. As such it will be interesting and valuable to biologists. An extensive bibliography, arranged under the headings that have been listed, will be of value to all biologists.

The Effects on Women of Changing Conditions in the Cigar and Cigarette Industries. By Caroline Manning and Harriet A. Byrne. Bulletin of the Women's Bureau, No. 100. United States Department of Labor, Women's Bureau. Paper. Pp. 187. Washington, D. C.: Supt. of Doc., Government Printing Office, 1932.

This study, made under the auspices of the United States Department of Labor, indicates the effects of the machines on the employment—or rather unemployment—of women in this industry. The book begins with a brief history of the tobacco industry. The manufacture of cigarettes began in 1864, with a total production of twenty million. Today production runs into billions. Most of this book is concerned with an analysis of the way in which unemployment has been brought about. For instance, there were 27,366 cigar manufacturers in 1900 but only 7,552 in 1930. A similar relative decrease took place in the number of cigaret factories. Nevertheless, in the same period of time the production of cigarets rose from 3 billion to 124 billion. During the same period the production of cigars increased only about 6 per cent.

Moderne Therapie der Neurosyphilis mit Einschluss der Punktionstechnik und Liquor-Untersuchung. Von Bernhard Dattner, Dr. med. et jur., Assistent der Klinik für Psychiatrie und Neurologie in Wien. Mit einem Vorwort von Hofrat Prof. Dr. J. Wagner-Jauregg. Cloth. Price, 22 marks. Pp. 334, with 53 illustrations. Vienna: Wilhelm Maudrich, 1933.

This monograph is an expansion of a series of lectures given by the author to English-speaking students. It bears a foreword from Wagner-Jauregg, under whose direction much of the author's work has been done. The major emphasis of the book is, as might be expected, on the fever treatment, particularly with malaria, of dementia paralytica. Comparatively little space is devoted to other methods of treatment or to the application of various types of treatment to other forms of neurosyphilis than dementia paralytica. The contents include descriptions of the technic of lumbar and cisterna puncture, of serologic tests on spinal fluid and their interpretation, of treatment methods (fever by various agents, chemotherapy, subdural treatment); of the application of these methods to and the results obtained in dementia paralytica, tabes, and cerebrospinal syphilis; and a discussion of the pathogenesis, prophylaxis and immune relationships of neurosyphilis. On the whole, the book is complete, compactly presented and valuable to the physician called on frequently to manage neurosyphilitic patients. Newer methods of inducing fever, such as diathermy and short wave radio, are briefly described and the author properly points out that, as compared with malaria, these and other physical fever-producing agents seem, on the one hand, to be less satisfactory than malaria and, on the other, to be as yet in the distinctly experimental stage. The method of presentation is appropriate either for the general practitioner or for the expert neurologist or syphilologist. The author displays more familiarity than many German writers with investigations in other countries; the bibliography of twenty-one pages contains references to forty-seven articles in English. It is regrettable that this monographic form of medical writing is not more widely practiced in the United States. It is an exceedingly valuable method of presenting a subject concisely and at the same time completely.

Economy in Higher Education. Part I: Principles. Part II: Administration. By David S. Hill, Staff Associate, Division of Educational Enquiry, the Carnegie Foundation for the Advancement of Teaching, and Fred J. Kelly, Chief, Division of Colleges and Professional Schools, the United States Office of Education. With a preface by Howard J. Savage, Secretary of the Foundation. The Carnegie Foundation for the Advancement of Teaching in Cooperation with the United States Office of Education, Department of the Interior. Paper. Pp. 127. New York: Carnegie Foundation for the Advancement of Teaching, 1933.

In this volume the Carnegie Foundation and the United States Office of Education have joined forces to analyze the influence of the present economic situation on the agencies of higher education. Publication was made possible by a grant from the Carnegie Corporation. The study consists of two parts, dealing, respectively, with principles and administration. Dr. David Spencer Hill of the foundation contributes part I; part II is the work of Dr. Fred J. Kelly, chief of the Division of Colleges and Professional Schools of the United States Office of Education. Under the caption "Urgent Issues" is presented a thoughtful discussion of the duties and responsibilities of administrative officers and boards of control. Economy and efficiency are defined and the major problem now confronting educational authorities is stated as "the necessity of effecting retrenchment with a minimum of educational loss." Elaborating this idea, Dr. Hill points out the dangers of hasty or sweeping reductions of salaries and indicates avenues by which budgetary adjustments may be accomplished with least risk of destroying permanent values. The President's Committee on Social Trends is quoted to the effect that the costs of education from 1915 to 1929 did not rise so rapidly as other governmental expenditures and that, in numerous ways, savings can be effected without jeopardizing the social function of colleges and universities. A plea is made for the reappraisal of educational aims and for the formulation of a sound philosophy to justify the use of public funds in the support of a coherent program of higher education. In the second part Dr. Kelly describes the waste involved in unnecessary duplication of institutions, departments and courses, especially when these have no more secure foundation than local or personal pride. He calls attention to the lack of means for determining the cost of research, which without question is a large but generally unrecognized factor in university budgets. The final chapter deals with some problems of institutional management, such as employment of personnel, salaries, accounting, purchasing and periodic reports. Nothing could be more timely than this candid presentation of the need for a clearer understanding of the social aspects of higher education, the mechanisms of public support, and the responsibilities of those officers vested with control.

A Study of Nephritis and Allied Lesions. By John Gray. Medical Research Council, Special Report Series, No. 178. Paper. Price, 2s. 6d. Pp. 141. London: His Majesty's Stationery Office, 1933.

The author has attempted to make a satisfactory classification of the nephritides by comparing the clinical histories with the anatomic conditions found after death. There is nothing new about this effort. The literature contains many similar attempts, the most noteworthy of which was made by Vollhard and Fahr. The present writer adds nothing to the exhaustive study of the German clinician and pathologist. He meets with the standard difficulty in all studies of this type, that the clinical course of the disease does not permit one to predict the anatomic disturbances, and vice versa. To overcome this impasse he deliberately selects what appeals to him from each group and rejects what does not fit into his program. In this study there is no attempt to search out etiology or to evaluate treatment.

Peptic Ulcer: Clinical Roentgenology. With Case Histories. By Jacob Buckstein, M.D., Instructor in Gastrointestinal Roentgenology, Cornell University Medical College. Volume X, *Annals of Roentgenology: A Series of Monographic Atlases.* Edited by James T. Case, M.D., Professor of Radiology, Northwestern University Medical School. Second edition. Cloth. Price, \$12. Pp. 417, with 404 illustrations. New York: Paul B. Hoeber, Inc., 1933.

In this edition, many new illustrations and important points have been added, and the literature has been brought down to date. The significance of the niche as a guide for the healing of an ulcer is well stated and amply illustrated. Frequent evidence of the disappearance of the niche in gastric and duodenal ulcers, under medical management, justifies a conservative attitude. The chapter on the study of the mucous membrane of the stomach and duodenum, under normal as well as patho-

logic conditions, is especially well presented. Each case is presented from the clinical, pathologic and roentgenologic phases of ulcer. The operating room and necropsy results are also provided.

Das Quecksilber: seine Gewinnung, technische Verwendung und Giftwirkung, mit eingehender Darstellung der gewerblichen Quecksilbervergiftung nebst Therapie und Prophylaxe. Von Dr. med. Ernst W. Baader, Dozent für Berufskrankheiten an der Universität Berlin, und Dr. med. Ernst Holstein, Gewerbemedizinrat in Frankfurt (Oder). Veröffentlichungen aus dem Gebiete der Medizinverwaltung, Band XXXX, Heft 1. Paper. Price, 12.60 marks. Pp. 239, with 21 illustrations. Berlin: Richard Schoetz, 1933.

This excellent monograph on industrial relations and toxicology of mercury is all the more welcome as it is evidently based on large personal experience. It contains, in addition to an interesting historical introduction, chapters on the chemistry and technology of mercury, the pathogenesis, symptomatology, pathology and treatment of mercurial poisoning, and the hygiene and legal requirements for the protection of those who work with this metal.

Medicolegal

Malpractice: A Tort or a Breach of Contract

(*Trammig v. Howard (Idaho)*, 16 P. (2d) 661)

The defendant-physician was treating the plaintiff for spinal meningitis. A needle that he was using in making an intraspinal injection broke and part of it remained in the patient's back. The defendant operated to remove the lost part of the needle and later he represented to his patient that it had been removed. When the accident happened, July 4, 1926, the plaintiff was a minor, about 19 years old. He became of age, May 13, 1928, and on April 3, 1931, about two years and eleven months later, he instituted this suit. In it he charged that the defendant had violated his contractual duty and had falsely represented that the part of the needle that had been broken off in the plaintiff's back had been removed. He claimed that he did not discover the falsity of the defendant's alleged misrepresentation until June 25, 1930. The defendant-physician, however, contended that the action, being an action based on malpractice, was an action in tort and was therefore barred by the statute of limitations. The trial court took this view of the case and dismissed the suit, and the plaintiff appealed to the Supreme Court of Idaho.

The complaint, said the Supreme Court, primarily alleges that the plaintiff and the defendant-physician entered into a contract for treatment. The defendant, however, did not expressly contract to use extraordinary skill and care, and only by implication agreed that he would use ordinary and reasonable care. That is only another way of saying that he contracted to discharge a duty imposed by law. Aside from the allegation of fraud on the part of the defendant, the basic allegations of the complaint are directed solely to carelessness, negligence and misconduct. The physician is not arraigned for a breach of his contract. He is arraigned for delinquencies in carrying that contract into execution. Those delinquencies, if they occurred, constitute nothing but malpractice, and the action is an action in tort, not an action for a breach of contract.

The plaintiff contended, however, that under the Idaho statutes (C. S. sec. 6611, subd. 4), a cause of action based on fraud does not accrue until the aggrieved party discovers the facts constituting the fraud and that he did not discover the alleged fraud in this case until June 25, 1930, less than two years before the action was begun. In order to invoke the statute cited by the plaintiff, said the Supreme Court, the action must rest solely on the fraud charged and the proof of that fraud must be essential to the granting of relief to the plaintiff. The statute with respect to the accrual of causes of action, relied on by the plaintiff, applies only to actions in which there is no injury except that arising out of the fraud itself. There was no merit in the plaintiff's contention that the alleged fraudulent concealment of the cause of action by the defendant stayed the running of the statute of limitations.

The action of the trial court in dismissing the suit was affirmed.

Medical Practice Acts: Discretion of Board in Granting Licenses by Reciprocity.—Ruffu, a graduate of a class C medical school, had been licensed to practice medicine in Illinois and sought a license by reciprocity in New Jersey. The New Jersey medical practice act authorizes the board of medical examiners, in its discretion, to issue a license without examination to a person who has been examined and licensed in another state, the standards of which when the applicant was licensed were substantially equal to those of New Jersey at that time. It was admitted that when Ruffu was licensed in Illinois the standards there were substantially equal to those then in force in New Jersey, but the New Jersey board nevertheless refused to grant him a license. Ruffu sought by mandamus to compel the board to do so. The only question to be determined, said the supreme court of New Jersey, is whether or not the board abused its discretion. Ruffu is a graduate of a class C medical school, a school not in good standing, in the opinion of the New Jersey board. He was therefore not eligible even for admission to an examination in New Jersey, for the medical practice act there requires every person admitted to examination to have the degree of doctor of medicine, conferred by a medical school which, in the opinion of the board, is in good standing when the degree is conferred. Under the circumstances, said the court, the board did not abuse its discretion in refusing to license Ruffu by reciprocity. His application for a writ of mandamus was rejected.—*Ruffu v. Board of Medical Examiners (N. J.)*, 163 A. 15.

Privileged Communications: Statement of Name of Attending Physician in Application for Insurance Not a Waiver.—A person who states in his application for insurance the name of a physician who treated him for a certain ailment does not thereby waive his right to have the information acquired by that physician in the course of attendance treated as a privileged communication. The privilege of secrecy may be claimed also by a beneficiary suing on the insurance policy.—*Novak v. Chicago Fraternal Life Ass'n (Kan.)*, 16 P. (2d) 507.

Evidence: Testimony of Expert Witness as Invasion of Province of the Jury.—An employee, who had broken his arm in the course of his employment, sued the defendant insurance company with which his employer carried indemnity insurance. The trial court refused to permit three medical experts, called by the insurance company, to state their opinions as to the extent to which the employee had lost the use of his hand. The proffered testimony, the trial court concluded, would be an invasion of the province of the jury. The insurance company appealed to the court of civil appeals of Texas, Amarillo. A medical expert, said the court of civil appeals, may not only give his diagnosis of the state of a person's health but also state his conclusion as to the cause of the injury or disease and make a prognosis concerning the physical condition. His opinion, when predicated on stated reasons, is admissible to show the extent of a personal injury. The object of all testimony is to prove the very fact to be found by the jury, and it is not usurpation of the powers of a jury to prove that fact. Since it was conceded that the physicians whose testimony was excluded by the trial court were qualified as experts and were in a position from observing and treating the employee to testify, it was error for the trial court to exclude their testimony.—*Zurich General Accident & Liability Inc. Co., Limited, v. Kerr (Texas)*, 54 S. W. (2d) 349.

COMING MEETINGS

American Association of Railway Surgeons, Chicago, August 10-12. Dr. Louis J. Mitchell, 29 East Madison Street, Chicago, Secretary.
Ohio State Medical Association, Akron, September 7-8. Mr. Don K. Martin, 131 East State Street, Columbus, Executive Secretary.
Washington State Medical Association, Seattle, August 28-30. Dr. Curtis H. Thomson, 1305 Fourth Avenue, Seattle, Secretary.
Western Branch Society, American Urological Association, Vancouver, B. C., August 3-5. Dr. George W. Hartman, 999 Sutter Street, San Francisco, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

17: 589-872 (March) 1933

- Review of Recent Literature of Tar Cancer (1927-1931 Inclusive). M. G. Seelig and Zola K. Cooper, St. Louis.—p. 589.
Idiopathic Osteosarthritis. L. S. Goin, Los Angeles.—p. 668.
Multiple Myeloma: Report of Five Cases. E. Scott, F. M. Stanton and Mary Oliver, Columbus, Ohio.—p. 682.
Genetic Studies on Transplantation of Tumors: IV. Linkage in Tumor 19308 A. J. J. Bittner, Bar Harbor, Maine.—p. 699.
Id.: V. Tumor 19308 B. J. J. Bittner, Bar Harbor, Maine.—p. 709.
Id.: VI. Tumor 19308 C. J. J. Bittner, Bar Harbor, Maine.—p. 717.
Id.: VII. Comparative Study of Tumors 19308 A, B and C. J. J. Bittner, Bar Harbor, Maine.—p. 724.
Ambivalent Effect of Single Acute Trauma on Growth of Transplanted Mouse Tumors. M. C. Marsh, Buffalo.—p. 735.
Embryonal Nephroma in Sheep. W. H. Feldman, Rochester, Minn.—p. 743.
*Melanoma of Scalp: Report of Case and Review of Literature. Ida J. Mintzer, New York.—p. 748.
*Improved Technic for Massive Tissue Culture. G. O. Gey, Baltimore.—p. 752.
Calculation of Dosage from Intracavitary Radiation. M. C. Reinhard and H. L. Goltz, Buffalo.—p. 757.
Four Gram Pack. M. C. Reinhard, Buffalo.—p. 763.
Calculation of Dosage from Radon Seeds. M. C. Reinhard and H. L. Goltz, Buffalo.—p. 770.
*Technic for Intensive Roentgen Irradiation of Neck. B. P. Widmann and J. L. Weatherwax, Philadelphia.—p. 777.
Life Size Outlines for Gynecologic Cancer Case Records. R. L. Dickinson, New York.—p. 784.

Melanoma of Scalp.—Mintzer reports a fatal case of melanoma of the scalp which illustrates how a benign pigmented mole that has been subjected to repeated trauma or chronic irritation may become transformed into a malignant melanoma. The lesion diagnosed clinically as "sebaceous cyst" and removed in 1928 was a fully developed melanoma, and the failure on the part of the surgeon to have the specimen examined is inexcusable. Recurrence was noted six months later, and death ensued a year after the recurrence had appeared. The first lesion was apparently localized, and the dissemination followed the second operation in spite of the roentgen treatment. In all probability, at the time roentgen therapy was given to the metastases in the cervical glands, there were metastases in the retroperitoneal glands and in the liver.

Technic for Massive Tissue Culture.—Gey outlines a method for massive tissue culture which consists in the utilization of the entire inner surface of the culture tube for the growth of the tissue cells implanted in it. In addition, it is possible to bring about a sort of washing action on the growing tissue cells by revolving the tube slowly at a controlled speed, thus allowing the supernatant fluid to bathe them constantly. The revolving action of the tube is brought about by a special device. The necessary slow movement has been found in preliminary experiments to be from one-half to one hour for each turn, or just enough to prevent a violent action of the supernatant fluid which would wash the growing cells free from the inner wall of the tube. By a simple adjusting mechanism the necessary slow movement can be varied and regulated to any desired speed. The method permits the maintenance of permanent strains of many types of cells in laboratories when sufficient technical help is not available to maintain the large numbers of cultures necessary when other methods of tissue culture now in use are employed. It eliminates to a great extent the cumbersome and detailed transfer technic involved when the cover slip method is used. As the entire medium is available for the growth of the cells contained in it, this simple roller tube method is economical, and the amount of medium used becomes almost directly proportional to the amount needed for the cultures it contains.

Technic for Irradiation of Neck.—The method of Widmann and Weatherwax for obtaining the sum total skin intensity resulting from the four direct beams, as well as the overlapping and transmitted radiation, is as follows: An anatomic cross section is drawn at the level of the desired central point of irradiation and enlarged according to the exact measurements of the patient to be treated; an isodose chart is applied to each of four portals anterior, posterior, right and left lateral. The depth of the dose to any part of the neck from all four fields can readily be ascertained. The isodose charts from four fields at right angles to one another will show that the total skin intensity is practically the same as the depth intensity and represents a homogeneous distribution of the radiation throughout the irradiated area. By clinical observation on a series of forty-seven cases, the authors found that the maximum safe dose which can be administered, within a period of eight or ten days, is 225 per cent skin erythema dose or 1,800 roentgens (as measured in air) to every part of the skin surface of the neck. Each skin intensity represents 100 per cent direct radiation.

Sclerosing Solutions in Cysts and Fistulas.—Cutler and Zollinger report cases of gliomatous cysts (astrocytomatous type), cervical fistulas and pilonidal sinuses in which they used a solution consisting of 6 cc. of absolute alcohol, 3 cc. of chloroform, 1 cc. of glacial acetic acid and 1 Gm. of ferric chloride, as a sclerosing agent. The application of the solution has either greatly assisted in making an operation more complete, in the cases of gliomatous cysts, or it has been able to cure the condition without radical surgery, in cases of cervical fistulas and pilonidal sinuses. The authors state that the successful use of a chemical substance without risk to the patient and without the disfigurement of a scar suggests that this method should have much wider application. It is of course in the field of small

fistulas with a lining membrane not more than a few cells deep that this method will find its greatest usefulness. They themselves were surprised at the success obtained in cases of pilonidal sinus. After opening the pilonidal sinus widely, thus allowing the fixative to reach and destroy all the epithelial surfaces, the destroyed lining of the cyst wall was curetted away. Since the patient can be ambulatory during the treatment and since excellent results have been obtained in their cases, they believe it worth while to attempt this method in most of the cases seen, for radical surgery can always be resorted to later. Their experiments in neurologic surgery have shown that the solution penetrates more quickly, produces less underlying encephalitis, makes thin cyst linings tougher and more easily handled, and is a better hemostatic agent.

Appendicitis in Pregnancy.—Marbury believes that every obstetric patient should be questioned concerning abdominal discomfort, with especial reference to the appendix. In doubtful chronic cases a barium meal followed by roentgenoscopy is helpful. In nonsuppurative cases during the first six months the outlook for both mother and child is excellent. Later the mortality increases directly as the duration in months of the pregnancy and the duration in hours of the appendicitis. Pregnancy is not an etiologic factor in primary appendicitis but tends to cause recurrences in which a pathologic condition already exists. Motion of the infant and the sag of the pendulous uterus are definite obstacles to the formation of adhesions and partially account for the frequency of generalized peritonitis. Early operation is the greatest factor in lowering mortality. Too much dependence should not be placed on a moderate temperature and leukocyte count, as these may give a false sense of security. A careful history, especially with reference to previous attacks, is of inestimable aid. The direct approach through a muscle splitting incision is advocated in nonsuppurative cases. In the presence of generalized peritonitis a cesarean section should be done, followed by the removal of the uterus, as in the Porro operation.

Adiposis Dolorosa.—Wilson points out that the fact that there have been no consistent observations in all the cases reported shows that adiposis dolorosa is not a clinical entity. It seems more reasonable to assume that the condition is one of either simple obesity or lipomatosis associated with neurosis or neurasthenia, and that the pathologic conditions found in cases that have come to necropsy were incidental. Whether obesity is to be explained on the basis of energy intake alone or energy intake and endocrine gland disturbances is not entirely settled. The preponderance of evidence points toward the latter. This is borne out by adiposis cerebri (Frohlich's syndrome), which is a disease of obesity associated with consistent pathologic changes in the pituitary gland. On the other hand, improvement in cases of adiposis dolorosa has been observed when the diet alone has been reduced. It is well, therefore, to look on adiposis dolorosa as a syndrome of lipomatosis or generalized or localized obesity associated with neurasthenia or neurosis. The treatment is symptomatic. The author reports a case.

Surgical Method for Relief of Pain.—Physiologic and clinical data convince Razumovsky that one can eliminate pain in neuralgia not only by means of dissection of sensory nerves but also by other means, such as various effects on the sensory receptors in neuralgia of peripheral origin, which apparently predominates, and on the pain conductors and the ganglion centers. He has previously reported his method of alcoholization for the treatment of neuralgia of the trigeminus; namely, the irrigation of the common carotid artery and its bifurcations, i. e., the beginning of the external and the internal carotid, aiming to affect the nerves in this artery and around it which reach the peripheral ramifications, the capillaries, and perhaps also the receptors. He has cured numerous cases of neuralgia by alcoholization, some cases having been observed during a period of two years. He has also observed some relapses and therefore he urges that the irrigation include the portion of bifurcation. He has also had good results in treating angiosclerotic gangrene, ischias, gastralgia, hepatalgia, neuralgia and painful tumors. The author believes that alcoholization will replace many serious operations, such as radicotomy, ramisection and chordotomy.

Bacterial Filtrates.—Nerb states that, in the intradermal injection of bacterial filtrates in genito-urinary infections, it is essential to have a 1 cc. syringe graduated in twentieths of a cubic centimeter, using either a Luer or tuberculin syringe and a three-fourths inch, 25 gage needle. The upper arm is usually chosen for the injection except in women, in whom it is given in the thigh. The injection is made by holding the needle parallel to the skin surface. With the oval point visible, it is inserted slowly into the papillary layer and the solution is slowly injected. If the injection is given correctly, a nontranslucent white wheal is produced, circumscribed, with a pinkish border. It is the author's practice to start with a small dosage, that is, 0.1 cc., and to increase it 0.1 cc. each time, until 1 cc. is given. It is better to give the injection every forty-eight hours and to keep the dosage smaller, not exceeding 0.5 cc. if a large local reaction occurs. Smaller doses may be given or the filtrate diluted twenty times. Besredka's bacterial filtrates, even if not specific, will increase natural resistance by stimulating the reticulo-endothelial system. It is essential, if stock filtrates are given, to define accurately the specific strain of the organism causing the infection. Bacterial filtrates have proved of value in gastro-enterology and in the treatment of infectious arthritis. Using freshly killed organisms and the bacterial filtrate as a diluent should prove of more value in intradermal treatment, since the soluble toxins are incorporated with the bacterial protein.

- Method of Recording Roentgen-Ray Readings. H. B. Pirkle, Rockville, Ind.—p. 311.

Climate and Altitude in Tuberculosis.—Phillips reviews the records of 309 patients with pulmonary tuberculosis, who during the winter resided in a sanatorium near Phoenix, Ariz., at an altitude of 1,079 feet, and during the summer months at an altitude of 5,300 feet, returning to Phoenix in October, in order to determine the effect of such a climatic change. Two thirds of the patients were classed as far advanced. Only the known hyperthyroid and those whose apneic pause was markedly shortened were denied treatment in the higher altitude. The seasonal cycle in which these patients lived was marked by reduplications of early summer and late summer, with dry air, abundant sunshine and comfortable outdoor temperatures throughout the year. The body weight curves of these patients showed a definite seasonal trend, apparently related to the length of the days and the intensity of solar radiation. They lost weight from April to July and gained during the other months. Body weight in this group was not governed by air temperature, relative humidity or percentage of possible sunshine, nor was it affected by the change of altitude in either direction. Women gained proportionately less weight than men and exhibited a wider seasonal variation in their weight. More than one third of the men and women alike, when moved from a low to a high altitude, showed a moderate acceleration of the pulse rate. This faster pulse was not accompanied by any increase in the clinical activity of their disease. The body temperatures of these patients, whether febrile or normal, were not affected by the change of climate and altitude. The incidence of pulmonary hemorrhage was almost exactly the same in the higher altitude as in the lower. A tendency to hemoptysis was not found to contraindicate the change, though all patients so transferred were kept unusually quiet during the period of adjustment.

Tape Test with Tuberculin Ointment.—Wolff outlines the technic for application and reading of a tuberculin-ointment tape test. The ointment is easier to apply and causes less psychic disturbance and fewer untoward reactions than does

old tuberculin in the intracutaneous method of testing. The agreement between the ointment test and the intracutaneous test in all dilutions, as applied to 190 children, was 95.8 per cent. The ointment test is generally comparable in results with the intracutaneous old tuberculin test in a dilution of 1:100. The technic is as follows: The area of application is the paravertebral region between the eighth and eleventh thoracic vertebrae. The skin is cleansed with green soap and water, dried, bathed with benzene and then dried again. A pea-sized drop of the semiliquid tuberculin ointment is applied on the right side, and a similar drop of the control ointment on the left side. Each of these drops is covered with a two-inch square of adhesive tape. The test is read in forty-eight hours. The adhesive tape is removed after soaking with benzene and the area is gently cleansed with benzene. Ten minutes after removal, the reaction may be clearly observed. A positive reaction exhibits papules, erythema, induration and pigmentation.

Dead Bone Grafts to Repair Skull Defects.—Pankratiev presents four case histories of skull repair by means of dead human bones, in one of which cranioplasty was performed because of a recent complicated skull fracture, with both an immediate and a final good result. In the second case, cranioplasty was used to cover an old defect causing traumatic epilepsy, and a disfiguring scar on the forehead. The result six months after the operation showed permanent improvement. In the third case, dead human bone was used because of an enormous skull defect 15 by 10 cm. in size, after the extraction of an osteosarcoma of the skull case. The operation proceeded smoothly, offering no difficulties, but the patient's unexpected inability to withstand the anesthetic prevents the author from reporting a case which he believes would have shown an excellent surgical result. In the fourth case, a congenital defect of a child's skull and cerebral hernia were successfully treated. The author concludes that the method is applicable both to fresh, noninfected wounds and to old bone defects with scar tissue. In the event that infection is anticipated, the application of cranioplasty seems inexpedient. The later suppuration of the wound would probably necessitate the extraction of the transplant, preventing a favorable result. Such defects as those formed after the extraction of bone skull tumors and in congenital cerebral hernia may be considered amenable to cranioplasty. In order to prevent the possibility of postoperative meningitis as well as acute purulent encephalitis, bone transplants of exact size and shape should be used and fastened with wire sutures.

Longitudinal Bone Growth.—Bisgard points out that, in normal experimental animals, longitudinal bone growth is not influenced by sympathetic deinnervation. Retarded bone growth in a monkey with residual paralysis from anterior poliomyelitis was not accelerated by sympathetic deinnervation. There is no experimental evidence to justify the use of the operation of sympathetic ganglionectomy for the purpose of accelerating bone growth. The three tried and proved methods of correction of length discrepancies of the extremities are shortening of the long extremity by osteotomy, longitudinal growth arrestment of the long extremity and lengthening of the short extremity by distraction.

Treatment of Malunion After Pott's Fracture.—Wagner states that correct alinement of all joint fractures should always be eagerly sought for and one should have no hesitancy in proceeding with open reduction in all fractures about the joints, if proper position cannot be secured by closed methods. The author has developed a type of open operative treatment for cases of malunion following unreduced Pott's fracture which corrects the vertical and transverse alinement of the ankle joint proper and which tends to throw the weight bearing in its proper normal line. The leg is prepared in the usual manner and a tourniquet is applied. The skin and subcutaneous tissues about the internal malleolus are divided and the lower end of the tibia is exposed. A similar incision is made over the external malleolus, but it is not necessary to expose the lower end of the fibula. The old fracture line of the deformed internal malleolus is removed with a chisel, a wedge of bone being taken out. A linear osteotomy of the lower end of the fibula is performed and the foot is placed in marked inversion, until the vertical and transverse alinement of the ankle joint is secured. The wedge of bone is reshaped and placed between the separated ends of the fibula and should hold the foot in its newly assumed corrected attitude. A plaster dressing is applied with the foot in marked inversion and should extend from the toes to the knee. At the end of six weeks from the date of operation, another cast is applied with the foot in slight inversion and the patient is encouraged to bear weight. Ten weeks from the operation, a caliper brace to fit in the shoe and extend to the knee is applied. Walking is encouraged in the corrected attitude. All support can be usually discarded about seven months after the operation, when all signs of traumatic arthritis of the ankle joint have disappeared.

Traumatic Ulnar Neuritis.—Conway believes that the lesions in which a disturbance of the normal relation between the ulnar nerve and its nerve bed exists may be grouped under the general heading of "traumatic neuritis." The clinical entity of late ulnar palsy is then to be regarded as being within this group. The condition is not common but is easily diagnosed in the light of a history of an old fracture about the elbow, followed years later by increasing weakness and atrophy of the hand. The original fracture is almost invariably a fracture of the external condyle of the humerus sustained during childhood. Of all the methods of surgical intervention, that of transplanting the ulnar nerve is by far the simplest and has given the most striking results. The author reports a case of ulnar neuritis in which the original fracture occurred twenty years before the development of symptoms and in which definite objective and subjective improvement was manifest as early as two weeks following the anterior transplantation.

Treatment of Sarcoma of Long Bones.—For osteogenic sarcoma, especially the type associated with marked new bone formation, Coley advises immediate amputation as soon as the diagnosis has been established. In order to lessen the chances of a recurrence, Coley's toxins should be given as a prophylactic for a period of six months. While endothelial myeloma is highly sensitive to both toxins and irradiation, rarely has the disease been controlled by irradiation alone. Toxins alone or toxins combined with irradiation have resulted in a large number of five-year recoveries, in some instances after the disease had reached the inoperable stage and metastases had developed. The author believes that a combination of the systemic effect of Coley's toxins and the local effect of irradiation offers the greatest hope of saving the patient's life as well as his limb in this type of tumor. Early amputation followed by prolonged toxin treatment would undoubtedly give a higher percentage of five-year recoveries, and for this reason it is well to let the patient have a voice in the final decision as to the method to be employed. In treating giant cell tumors of the long bones he advises early and thorough curettage, swabbing out the cavity with a 50 per cent solution of zinc chloride or phenol and alcohol, closing the wound without drainage, and then on the third or fourth postoperative day starting a short course (four weeks) of prophylactic toxin treatment to be given in moderate doses. Primary amputation or resection should almost never be performed in this type of tumor. His series contains many cases in which large areas of bone destruction were completely restored by nature, showing that resection and bone grafting are unnecessary. He reports a series of 360 cases, which includes

a large number of inoperable, hopeless cases in which recovery occurred under treatment and the patients have remained well for more than five years, and nineteen permanent recoveries that took place prior to 1913.

Treatment of Epithelioma of the Lip.—Elliott treated sixty-six cases of primary epithelioma of the lip by electrocoagulation and irradiation. In none of the cases has there been a local recurrence or metastasis to the lymph nodes. In one case a possible metastasis to the brain developed seven years following the removal of the lesions on the lip. Electrocoagulation and irradiation offer a high percentage of cures in early epithelioma of the lip. The end-results are as good as, if not better than, those obtained by any other method of treatment. The dermatologist by virtue of his diagnostic ability is in a preferred position to treat such lesions.

Sodium Dehydrocholate in Arsphenamine Poisoning.—Appel states that sodium dehydrocholate is a choleric drug, nontoxic in 10 cc. doses of a 5 per cent solution administered intravenously at intervals of several days. It has been used to combat the toxic action of arsphenamine and its derivatives on the liver. In five cases of jaundice which developed during antisyphilitic treatment with neoarsphenamine, the patients were treated with intravenous injections of sodium dehydrocholate. There was a prompt fall of the icteric index, with rapid recovery. The author suggests that the effect may be caused by the washing of arsenic from the liver, as the result of increased cholestasis. In a number of cases in which nausea and vomiting followed intravenous injections of neoarsphenamine, the patients were treated by mixing the solution of the drug with a solution of sodium dehydrocholate and injecting the mixture intravenously. The majority of the patients showed no reactions following these injections. One case is reported in detail.

Pseudoxanthoma.—Jones and his associates discuss the previously reported cases of pseudoxanthoma elasticum of the skin and point out the observations of others relating to the peculiar association of this condition with angioid streaks of the retina. Five of their cases are reported, all of which showed angioid streaks of the retina. The histopathologic pictures of the excised skin of pseudoxanthoma elasticum, senile elastosis and lineae albicantes are presented with observations on the similarity of the appearance of these conditions in all instances. The authors conclude that the association of angioid streaks of the retina and pseudoxanthoma elasticum is a frequent occurrence, that the pathologic appearance of the latter aids in a theoretical explanation of the former, and that pseudoxanthoma elasticum is a disease allied to the process that produces elastic tissue degeneration in some scars and in senility. They have found nothing in their studies to indicate that this condition is in any sense neoplastic. While there is an overgrowth of elastic

fibers as well as degeneration, microscopic studies fail to show any neoplastic characters, and the clinical features of the cases seem to bear this out.

Lichen Planus.—Jacob and Helmbold isolated a gram-negative, anaerobic bacillus from twenty-five of twenty-eight cases of lichen planus. Semisolid dextrose serum agar containing cubes of human tissue was the medium used. The serum used must be inactivated at from 56 to 60 C. for a number of hours. The organism was not found in normal skin or in a number of cases of other papular diseases used as controls. Inoculation of human skin with this organism, in a few instances, produced lesions which both clinically and histologically resembled lichen planus. The organism could be easily demonstrated in section in the exudate of lichen planus lesions incubated for forty-eight hours or more.

Meningococcic Meningitis and Meningo-Encephalopathy.—Kempf and his associates present sixty-eight cases that do not conform to any of the described clinical entities as an acute epidemic meningo-encephalopathy in which there is a macrophagic and leukocytic response. Of the sixty-eight cases, twelve were fulminating, thirty-five less acute, and twenty-one mild. Patients in the fulminating group continued in convulsions, became comatose and died from twelve to forty-eight hours after the onset. Occasionally a patient improved after spinal drainage and the intravenous administration of dextrose. The temperature in most of these patients rose rapidly to as high as 108 F. or dropped below normal—in one instance going as low as 94.5 F. In the less severe type the patients improved rapidly after spinal drainage and frequently came out of stupor or coma after one or two punctures. In these patients the temperature, if elevated, rapidly approached normal after one or more spinal drainages. The course then showed little fever and few symptoms unless drainage was stopped. Even when the spinal fluid pressure was normal or low, drainage relieved the severe headaches from which the patients suffered. Most of the patients with the mild type of infection improved remarkably after daily spinal drainage. Several psychopathic patients contracted the disease through contact with other patients in whom it had been unrecognized; in them the mental symptoms did not improve. The mortality rate for the first sixty-eight cases was 39.7 per cent; it has since continued below 40 per cent.

Treatment of Athetosis and Dystonia.—Putnam brought about a decrease in the abnormal movements by operative section of the prepyramidal and anterior quadrant marginal fibers, or the latter alone, of the cervical cord in two cases of familial dystonia musculorum, one of bilateral choreo-athetosis following an acute infectious disease in infancy and one of unilateral athetosis following an acute infection in adult life. The operation was followed by mild signs of pyramidal tract defect in one case and hemianalgesia in another. There were no permanent ill effects from the operation and (except in one case) no sensory loss. In a case of juvenile paralysis agitans following encephalitis, the symptoms were neither relieved nor aggravated by the operation.

Ménière's Disease.—During the past two years, Coleman and Lyerly divided the eighth cranial nerve in eleven patients for the relief of Ménière's disease. The diagnosis is based on a history of attacks of violent vertigo accompanied by nausea and vomiting, tinnitus in one ear and partial deafness in the same ear. The operation for relief of Ménière's disease presents no great difficulties to those experienced in neurologic surgery. A curved incision is made over the suboccipital region on the affected side from a point on a level with the tip of the mastoid process and running upward, then inward and downward to the midline. It is important to place the bony opening laterally as far as possible without entering the mastoid cells, because the most direct approach to the cerebellopontile angle is along a line parallel to the posterior surface of the pyramid. Every effort should be made to avoid hemorrhage about the nerve. The arachnoid covering should be carefully removed before an effort is made to separate the eighth nerve from the facial nerve. If a hemorrhage about the nerve occurs on division of the eighth nerve, facial paralysis is likely to result. The exposure of the nerve should be adequate. Forceful retraction should be avoided if the facial nerve is to be protected from damage. The auditory nerve is first examined for abnormalities and is then hooked up and divided with a long, sharp-pointed knife. No attack of vertigo has followed the operation in any case, although some of the patients have had a slight unsteadiness, particularly on sudden change of position or quick movements. This unsteadiness tends to improve with time and is not disabling. Tinnitus, when not entirely abolished by the operation, has been changed and improved in every case. The authors conclude that intracranial section of the eighth nerve is highly successful in relieving the disability of Ménière's disease.

Hour-Glass Tumors of Spine.—Naffziger and Brown state that hour-glass tumors of the spine occur with far greater frequency than is indicated by the literature on the subject. They are so common that, in making a diagnosis of compression of the cord from tumor, the possibility of the tumor being of hour-glass type should be kept in mind. In the neck, careful palpation may reveal an extravertebral mass. In the dorsal and lumbar regions, as well as in the cervical region, diagnosis is aided by roentgenograms, which should include views of the intervertebral foramina and the interlaminar and interspinous spaces. Deformity of these is suggestive. The majority of hour-glass tumors are encapsulated. In some instances, complete removal of the intraspinal and extraspinal portions at one stage may be possible; in others, second-stage operations for the removal of the extraspinal portions may be required. Thoracic tumors have been removed, only to be followed by hydrothorax resulting from clear cerebrospinal fluid because the tumor was not recognized as being of the hour-glass variety and the dura was torn. The authors add fifteen cases to the sixty-eight that they reported previously.

*Auricular Flutter with 1:1 Response. Caroline C. Bedell, Baltimore.—p. 225.

Acquired Immunity in Syphilis.—The rabbits that Rich and his associates rendered immune to syphilis by inoculation with *Spirochaeta pallida* showed no allergic reaction whatever, whether macroscopically or microscopically, on intracutaneous reinoculation at periods ranging from 28 to 482 days after the primary, immunizing infection. On the contrary, the most striking phenomenon observed in the immune animals, as contrasted with the nonimmune controls, was always a remarkable indifference of the tissues of the former to the presence of the injected virus. Although allergy to *Spirochaeta pallida* is well known to appear during human syphilitic infection and can also be induced in the rabbit, according to Noguchi, the present experiments demonstrate that allergic inflammation is not necessary for the operation of acquired immunity in syphilis.

Auricular Flutter.—Bedell describes paroxysmal attacks of 1:1 response occurring during the course of auricular flutter in twenty-four cases. Three of these cases are reported for the first time, with electrocardiograms and tabulated analysis of the records obtained; the remaining twenty-one cases have been gathered from the literature. The twenty-four cases have been subdivided into three groups in which the mechanism seems somewhat different: 1. Two cases characterized by rapidly increasing auricular tachycardia in which 2:1 block appears shortly after a rate of from 240 to 273 is reached. 2. Four cases resembling paroxysmal auricular tachycardia, but with heart rates ranging from 212 to 244. There is no definite evidence that these are instances of auricular flutter. 3. Eighteen cases, forming a unified group, from which the characteristics of 1:1 flutter were adduced. The author observed that a 1:1 flutter occurs most frequently in the fifth decade of life; it has not been observed above the age of 57, in contrast to other forms of auricular flutter, which may occur after the age of 70. In other respects, the etiology is not dissimilar. The 1:1 paroxysms occur during the course of established auricular flutter in which a high grade of block is not established, often with increasing ease and frequency. The attack begins abruptly following exertion. Extreme weakness, shortness of breath and palpitation are the usual manifestations. Syncope, precordial pain and congestive failure may occur. After minutes or hours, the attack subsides gradually. Attacks have followed the administration of quinidine, as well as the combination of atropine and tribrom-ethanol. The attacks of syncope and the possibility of congestive failure during frequent paroxysms somewhat modify the general prognosis in flutter. Digitalis effectively prevents 1:1 paroxysms by increasing the auriculoventricular block. During quinidine administration the patient should be kept in bed because of the possibility of paroxysms.

Suprarenal Cortex Extract in Treatment of Bronchial Asthma.—Fineman treated four patients who had severe asthma (three protein sensitive and one nonsensitive), for a period of from one to twenty-seven months, with little or no improvement. He then used suprarenal cortex extract, beginning with a dosage of 0.5 cc. and increasing it up to 4 cc. Injections

were given three or four times weekly during the first month and once or twice weekly thereafter. Subcutaneous and intramuscular injections were administered in each case. Two patients received treatment for four months, one for three months and one for six weeks. One patient showed marked improvement in asthma, one moderate, one slight and one no improvement. In three of the patients a decided increase in strength and appetite was noted, with an average gain in weight of $4\frac{1}{2}$ pounds (2 Kg.). The general condition of the patients was definitely improved. No appreciable change in blood pressure was noted during or at the end of the course of treatment. No influence on the pulse rate was observed. The author believes that the results obtained with the suprarenal cortex extract in the treatment of these four patients warrant its further trial in a larger series of cases, employing larger dosage and utilizing, if necessary, the intravenous route.

Tubercle Bacilli in Sputum of Children.—Friedman and his associates present a study based on a group of sixty children, fifty-one of whom were admitted as preventorium patients and nine for tuberculosis of joints; two children—representing 3.33 per cent of the entire series, or 4.56 per cent of those with a positive tuberculin reaction—showed tubercle bacilli in their sputum. Of the group, forty-four reacted to tuberculin and only seventeen presented definite roentgenologic evidence of the childhood type of infection. No child in the series gave clinical or roentgenographic evidence of pulmonary infiltration. The two children whose sputum was positive for tubercle bacilli differed in no way from their associates. Each of these two patients gave a history of contact with tuberculosis, was a reactor to tuberculin, had only questionable roentgenographic evidence of the nodular type of infection and was free from cough, expectoration, fever and tendency to colds. The tubercle bacilli could not be detected by examination of a pharyngeal smear obtained after forced coughing, or by means of the direct examination of the homogenized sediment of the gastric washings. They were found only on guinea-pig inocula-

tion of the homogenized sediment of their gastric washings. Tubercle bacilli were not observed in smears of the homogenized gastric washings of five children presenting the adult type of pulmonary tuberculosis whose sputum was repeatedly positive for tubercle bacilli by ordinary methods.

Roentgen Treatment of Inflammatory Conditions in Childhood.—Levin has found roentgen radiation to be a valuable form of therapy in whooping cough, asthma, pneumonia and unresolved pneumonia, acute lymphadenitis, parotitis, otitis media and mastoiditis, cellulitis, erysipelas and pyogenic skin infections of children. No deleterious effect from roentgen treatment has been reported in the literature in cases of this type, when the proper technic and correct doses have been used. It is necessary to emphasize that the value of the x-rays is greater when used early in the disease and that the treatment should be given by a competent therapeutic radiologist. In the author's experience, this form of treatment was especially satisfactory in acute lymphadenitis and early mastoiditis. The use of roentgen therapy in the treatment of inflammatory conditions in childhood is deserving of greater and more widespread trial.

Newer Concepts in Cancer Treatment.—Behan describes twenty different methods of treating cancer, each of which has had its advocate who claimed success by its use and most of which are to be used only in association with surgery and irradiation. Among the single means of treatment of cancer, surgery apparently has the greatest percentage of cures; even though in some cases its primary mortality is high, yet it is in nearly all cases the treatment of choice. Surgery, irradiation, ligation, calcium, and perhaps some of the heavy metals, and local treatment, i. e., desiccation and cauterization, will give the best final results in the treatment of cancer. One should remember that the host to the cancer is the patient and that his resistance is inviolable and must not be reduced but should, if possible, be increased. Peace of mind, quiet, proper food, blood-forming preparations, hope and rest are essential to cure.

Study and Treatment of Sterility.—According to Titus, the successful treatment of relative sterility depends on an accurate and complete diagnosis of its causes, usually multiple. This study is incomplete unless all steps in a certain, systematic investigation of both husband and wife are carried out. Absolute sterility may be attributed usually to a single gross cause, whereas relative sterility will usually be found due to a combination of minor causes which merely lower the "fertility index." Foci of infection and anemia contribute to lowered physical condition or vitality; minor gynecologic lesions, such as endocervicitis and leukorrhea, often play a major part, and these lesions in particular should be corrected by cauterization, conization or operation. Gross lesions, such as retrodisplacements, fibroid tumors or ovarian cysts, contribute to lowered fertility, while tubal occlusion from adnexal disease results in absolute sterility. The physical examination of the husband may show undescended testes, epispadias or hypospadias and is therefore important. The last two anatomic faults possibly can be overcome by the use of condoms with an orifice cut at a corrective point. The Hühner test gives the greatest possible information as to male responsibility. The wife is asked to report to the office an hour or so after coitus. A small amount of spermatic fluid is recovered from the cervix by a narrow suction syringe and examined microscopically under low power magnification. Many active spermatozoa should be seen. The Rubin insufflation of the tubes is not always merely diagnostic

but in certain instances actually proves to be a therapeutic measure. Passage of gas through the tubes at low pressure, such as from 60 to 80 mm. of mercury, indicates normally patent tubes; the other extreme, no flow despite pressure up to 200 or 210 mm. of mercury, is fair evidence of occlusion. Roentgen visualization after injection of iodized oil serves to localize the site of the lesion. Tubes occluded only at their outer ends, as the result of appendicitis in girlhood, may be opened and repaired by a plastic operation if the patient desires it, whereas tubes completely occluded, because of gonorrhea, are obviously beyond help in this respect. A lowered basal metabolic rate in the wife and husband should be corrected by thyroid extract, because underactivity of the thyroid is frequently associated with other glandular disturbances. The judicious administration of thyroid extract to the lacking wife or husband has frequently been followed by pregnancy.

Pulmonary Tuberculosis and Anorectal Fistulas.—In a bacteriologic and histologic study of tissue in 155 cases, in which 106 patients were free from evidences of pulmonary tuberculosis, eighteen had an inactive arrested fibroid phthisis and thirty-one had an active pulmonary tuberculosis, Chisholm concludes that tubercle bacilli are found in patients with ischio-rectal abscesses or anorectal fistulas only if pulmonary tuberculosis is present. He found tubercle bacilli in 77 per cent of the patients with active and in 55 per cent of the patients with inactive (arrested or fibroid) pulmonary tuberculosis, but they were not isolated in the 106 cases in which the patients were free from evidences of pulmonary tuberculosis. These observations suggest a close etiologic relationship between tuberculous ischio-rectal abscess or anorectal fistulas and pulmonary tuberculosis. Histologic methods were found unreliable for determining the tuberculous nature of anorectal conditions, except possibly in the presence of marked involvement with typical tubercle formation and the presence of acid fast bacilli, which was not a common observation in the author's series. The presence of giant cells or granulomatous tissue with monocytes and epithelioid cells proved not definitely pathognomonic of tuberculosis in the anorectal region. Acid fast bacilli are not commonly found in sections or smears from tuberculous ischio-rectal abscesses or anorectal fistulas with the aid of the microscope, even though they are readily found by reliable culture methods or guinea-pig inoculation.

Pulmonary Air Cysts of Infancy.—Anspach and Wolman report two cases of lung cyst observed in infants: one of the cysts originated as a large chamber filled with lymphangiectatic fluid, which evacuated spontaneously and then "ballooned out" with air, producing a fatal outcome; the other, which was not verified by necropsy, showed a constant roentgenologic appearance over a long period. Fluid cysts in infants, which are

usually mistaken for atelectasis, do not have a characteristic roentgenologic appearance, but lung tissue containing air about an area of increased density should arouse suspicion of the presence of a cyst. The diagnosis of balloon cysts depends on successive roentgen and clinical studies and on an understanding of the late stages of pathogenesis. Usually an erroneous diagnosis of pneumothorax has been made. The main roentgenologic diagnostic points of a balloon cyst are the presence of lung tissue at the apex and angles and its absence at the usual hilus region. A collapsed retracted lung shadow, as in simple massive pneumothorax, is not seen on the film. Small air cysts that cannot be differentiated from other air pockets, such as localized pneumothorax, will maintain a more or less constant appearance at a single examination, while the others will show changes and later disappear. On the basis of a study of reported cases and of their own observations, the authors believe that congenital air cysts of the lung contain fluid at birth, and that their postnatal behavior depends principally on mechanical factors.

Incision for Resection of Sympathetic Ganglions.

White and his associates outline a new oblique muscle-splitting incision, which in their hands has avoided much unnecessary bleeding and trauma of the large muscles of the back. The skin incision is made starting a finger's breadth lateral to the spinous process of the seventh cervical vertebra and running obliquely downward and outward over the medial angle of the scapula. This incision need not be more than 8 cm. long. In the case of a bilateral operation, a similar incision is made on the opposite side. The cut is carried down to the deep fascia, and bleeding points are ligated. The incision runs nearly parallel to the fibers of the trapezius, which are now separated by cutting through the fascia and stretching with the fingers. The fibers of the trapezius are then retracted upward and downward, thus exposing the minor rhomboid and levator anguli scapulae muscles. These muscles are separated by blunt dissection and then drawn apart by a pair of retractors. When the serratus posterior superior muscle is split, the three upper ribs and the deep longitudinal back muscles are exposed. The attachments of these deep muscles are then separated from the transverse processes corresponding to the first and second ribs and drawn back by a medial retractor. The resulting exposure gives ample room for resection of the proximal portions of any of the three upper ribs. Generally speaking, if one intends to remove a portion of the cervicothoracic sympathetic trunk extending from above the inferior cervical ganglion to below the second thoracic ganglion, it is easier to reach the upper portion of the trunk through the first rib and the lower portion of the trunk through the second rib. However, as a rule, this portion of the trunk can be resected through either rib. Occasionally, in difficult cases, it is best to remove both. After removal of the rib and transverse process, the pleura is separated from the body of the vertebra with blunt dissection. For this purpose, the operator's index finger is the ideal instrument. The pleura must be separated to a depth of 3 cm. and can best be retracted by the use of a brain spoon. At this depth the sympathetic chain is usually seen running longitudinally and adherent to the sides of the vertebral bodies. If it cannot be located in this way it can be found by search for the sympathetic rami, which leave the second intercostal nerve and join the sympathetic trunk about a centimeter deeper down. Once the trunk is located, it should be drawn up on a nerve hook and followed both upward and downward by blunt dissection. Through either a first or second rib resection it is possible to follow the trunk downward and cut it beneath the small second thoracic ganglion. Then with downward traction and by successive cutting of the small sympathetic rami as they leave the trunk, it should be possible to visualize two large ganglions higher up. It is important to have a good exposure in order to avoid injury to the first thoracic nerve. After the large ramus joining the first thoracic ganglion to its spinal nerve is cut, it is not difficult to draw the sympathetic trunk downward to a point where the inferior cervical ganglion can be safely dissected out. The incision is closed tightly unless persistent oozing demands drainage. As the retractors are removed, the muscle edges fall together and require only a few interrupted catgut sutures for perfect apposition. A row of interrupted sutures through the deep fascia of the trapezius, and silk sutures for the skin, complete the operation.

Acute Disseminated Lupus Erythematosus.—Roxburgh reports a study of five cases of acute disseminated lupus erythematosus, all fatal. The disease is more common in women than in men and in patients between 20 and 30 years of age. Most cases begin as the chronic localized type of lupus erythematosus. There is no evidence to show why they change to the acute disseminated type. There is no way of telling whether any given case of chronic fixed lupus erythematosus is likely to change to the acute type. Arthritis, arthralgia and muscular pains, albuminuria, a purpuric type of eruption and high temperatures are of evil import if occurring in a case of lupus erythematosus, as they suggest the onset of the fatal stage of this disease. No assistance in diagnosis is forthcoming from the leukocyte count, which is within normal limits, or from blood cultures, which are usually sterile until near the end. After the onset of acute symptoms, death is not likely to be delayed more than from one to four months. The cause of death is streptococcal septicemia. Tuberculosis has nothing to do with this form of the disease.

*Prevention and Treatment of Urethral Stricture of Inflammatory Origin. J. C. Ainsworth-Davis.—p. 1.

*Carbuncle of Kidney: Report of Two Cases of Bilateral Involvement. F. S. Patch and R. G. Reid.—p. 34.

Urethral Stricture of Inflammatory Origin.—Ainsworth-Davis states that stricture of the urethra is due to imperfectly treated gonorrhea and may take years to develop. Stricture and its complications are of such a serious nature that every effort should be made to ensure early diagnosis and treatment. Unfortunately, symptoms are rarely experienced before the caliber of the urethra has been reduced to about one third of its normal size; i. e., 15 Charrière. Stricture is curable, provided treatment is carried out in the right way, which consists in making it retrace its own footsteps by regular instrumentation: this gradually brings about rupture of the inner layers of fibrous tissue, which are then absorbed during the intervals of treatment. Efficient local anesthesia renders this treatment painless, a great factor in ensuring regular attendance. Late diagnosis and the presence of complications call for the use of a variety of periurethral instruments. Neglected cases and the occurrence of certain severe complications may necessitate operations, sometimes immediate, as a life saving measure. The best procedure is suprapubic cystostomy, any direct operative attack on the stricture being avoided at the time, and an attempt being made by instrumentation at a later date. The author summarizes the treatment of certain preinstrumental and postinstrumental complications of stricture, such as urethral discharge, urethral flakes, prostatitis, vesiculitis, epididymitis, periurethral abscess, fistula, false passage, extravasation, hemorrhage, "catheter" fever, retention of urine, and the breaking off of a guide.

Carbuncle of Kidney.—Patch and Reid report two fatal cases of bilateral renal carbuncle, both proved by necropsy. One of the cases showed a typical carbuncle of the liver. They also report two cases of presumable renal carbuncle with peri-

nephric abscess. Both patients recovered following drainage of the abscess. The value of the pyelogram in arriving at a diagnosis has been demonstrated in the two cases of presumed renal carbuncle. The authors' two cases emphasize the advantages of early diagnosis and conservative therapy. In all obscure cases, when even slight signs and symptoms suggest urinary tract involvement, a full urologic study should be made.

Modified Bendien Reaction in Cancer.—Lowe describes a quantitative modification of the Bendien test for cancer. He employed this method in 362 cases presenting various degrees of malignancy, ranging from the most advanced and obvious to the earliest and clinically uncertain type. The primary tube reaction showed it to be insufficient for the diagnosis of a malignant condition. The triple test (the author's modification) must be employed and will then differentiate malignant from nonmalignant conditions in at least 95 per cent of cases. The clinical diagnosis and the degree of positiveness shown by the test closely correspond. Postoperative cases of cancer, or those receiving radium, roentgen, or other forms of treatment, may be followed up by means of this test, and clinical information may thereby be obtained regarding prognosis and treatment. The author refers to cases in which satisfactory clinical improvement and apparent cure is associated with the continued presence of a normal or nonmalignant serum reaction. In some cases the serum reaction has foretold a recurrence months before clinical observations have confirmed it. Among normal and clinical nonmalignant conditions a certain percentage of abnormal reactions occur, suggesting the possibility of recognizing in such cases a precancerous tendency. The test is delicate and reliable, more satisfactory as a laboratory technic than any other at present available, and should be of value as a clinical aid to the diagnosis and prognosis of malignant conditions, especially in early cases.

Variants of *Clostridium Welchii*.—McGaughey isolated two variants from an authentic strain of *Clostridium welchii*, by selection and repeated subculture of colonies, which have remained stable during a period of observation of about four years. The variants differed from the parent strain and from one another in form of colony, growth in broth, size and shape of individual bacilli, sporulation and formation of capsules. They resembled the parent strain and one another in fermentation activity, giving an acroline test, liquefying gelatin and

producing a stormy clot in milk. At one stage one of the variants appeared to be incapable of producing toxin but later produced small amounts of toxin in culture. The other variant produced from three to six times as much toxin as the parent strain. The production of hemolysin in culture followed exactly changes in the production of toxin. By agglutination tests the antigens of both variants differed completely from the parent strain. The antigens of the variants were closely related and perhaps identical. Mucoïd types of the parent strain and of both variants have been noted. The importance of these results in the production of *Clostridium welchii* toxin and their possible application to the study of *Clostridium welchii* infection and immunity is suggested.

*Streptococcal Meningitis: Case with Recovery. J. K. Rennie and W. S. Craig.—p. 524.

Treatment of Enlarged Tonsils in Children.—Layton doesn't believe that there is as yet any local treatment of the tonsils that can compare with operative surgery. Size is no indication for removing tonsils. The great indication is the history of recurring follicular tonsillitis, and this is more important than any appearance of the tonsil. Children need lymphoid tissue in their respiratory tracts, and they do not get follicular tonsillitis in the earlier years of life. Therefore, operations on a child up to 5, 6, 7 and 8 years of age should not be done unless it cannot possibly be helped and the need for it can be proved. After that age the operative treatment of the tonsils is a practical problem, but the author thinks that the best results come after the age of 12 rather than before.

Prognosis in Tuberculosis.—In his follow-up study of 500 consecutive cases of pulmonary tuberculosis extending over a period of six years, Trail found that considerable value must be given to the sedimentation rate in assessing ultimate prognosis. It is usual to assess such prognosis on physical signs, temperature, pulse, sputum tests and the patient's fitness for exercise judged on the results of "exercise tests." It is well known how such criteria can lead the physician astray, but the sedimentation rate may be a decided help, since the prognosis becomes increasingly grave with the higher rates of sedimentation. If a patient enters the sanatorium with a figure of more than 20 and leaves with a figure of more than 10, it means a grave prognosis; this applies to all patients presenting clinical tuberculosis, "open" and "closed," and, while the gravity increases in positive tuberculosis and, in particular, in those who remain so in spite of treatment, it appears that it is better for the patient to remain positive and secure a fall in the sedimentation rate to less than 10 than to become negative with a discharge figure of more than 10. Artificial pneumothorax reduces the sedimentation rate: the average fall in twenty cases was from 31 per cent to 14 per cent. Rest is the best of all treatments. Once the patient has been assessed, the amount of rest required, the capacity for increasing movement in "graduated rest," and the fitness for the return to work ought to be based as much on the movements of his sedimentation rate as on his pulse, temperature, "exercise tests," and sputum results. Both immediate results and after-results may be benefited and the physician may be distinctly aided in his difficulty of the evaluation of prognosis.

Streptococcal Meningitis.—Rennie and Craig report a case of streptococcal meningitis and state that a striking feature of the more recent cases, and one well exemplified in their case, is the rapidity of progress, once improvement is established. How far this is due to the use of the various serums is difficult to say, but it seems more than likely that they exercise an influence on the course of the disease. Lumbar puncture alone or in combination with some other method is the procedure most generally adopted. Operative measures—e. g., mastoidectomy and labyrinthotomy—have been employed, but only when the source of the infection lay in the ear. When a block in the spinal canal has taken place and little fluid has

been obtained by lumbar puncture, cisternal puncture has been resorted to. In several cases antiseptics were used to wash out the spinal canal: acriflavine hydrochloride and a 1 per cent solution of mercurochrome. More recently, serum has been administered in addition to any other procedure. Of the serums employed, the antimeningococcus serum has been used most frequently in the first instance before a report on the cerebrospinal fluid has been obtained, and in one case (Ebert) recovery followed the use of this serum alone. Once the true state of affairs has been recognized polyvalent antistreptococcus serum has been extensively used, and results have certainly been better since its introduction. In streptococcus antitoxin (scarlatina) globulins, which has more recently become available, one has probably a much more potent agent. The authors believe that the intramuscular administration of 20 cc. of scarlatinal serum was responsible for their patient's rapid recovery, although large doses of polyvalent serum were previously administered.

Aplastic Infantile Anemias.—Morquio and Volpe report eight cases of infantile aplastic anemia which were confirmed by necropsy. This hemopathy is characterized clinically by a grave anemia appearing insidiously under the symptoms of asthenia, loss of appetite, slight loss of weight and rapidly increasing pallor. It is usually accompanied by purpuric manifestations varying from petechial eruptions to intense, repeated eruptions having the aspect of a severe primary purpura haemorrhagica and diphtheroid necroses. These were seen in only one of the authors' cases in the form of a Vincent's angina but have frequently been reported in adults. Hematologically this anemia is characterized by an erythroleukothrombopenia. There is an absolute absence of erythroblasts of all kinds, and all signs of erythrocytic regeneration are completely lacking. The leukopenia is characterized by an absolute and relative lymphocytosis and a granulocytopenia which may be marked, showing an absence of myeloid reaction. There is no decrease of globular resistance and there are no signs of hyperhemolysis. A positive diagnosis of aplastic anemia demands the absence of phenomena of hyperhemolysis and the confirmation of a myeloid aplasia as the cause of the aregenerative blood formation. This is obtained by medullary biopsy, by tibial or sternal trepanation which shows, macroscopically and microscopically, atrophy of the bone marrow and absence of all hematopoietic activity. Differential diagnosis involves primarily certain cases of aleukemic lympholeukosis and preleukemic or atypical leukemic states in which the clinical manifestations of anemia and the hematologic manifestations of erythropenia dominate while the leukocytosis is nearly normal and the lymphocytosis presents only rare embryonic cells of the lymphoblastic type. There is no doubt about the diagnosis if the evolution is definitely toward the leukemic formula; if it is not, the diagnosis can be made only by

medullary biopsy or necropsy. Clinically, this cryptogenic anemia, once it is established, progresses rapidly and is not arrested by hepatotherapy, transfusions, or roentgen therapy in stimulating doses. In six of the cases of infantile aplastic anemia seen by the authors, the course of the disease was acute; the period between the first perceptible signs and death varied between two and three months. Only one case had a slow evolution lasting eight months.

Metabolism of Iron in Breast-Fed Infants.—Wallgren conducted twenty-one experiments on the metabolism of iron in five nurslings between the ages of 3 weeks and 11 months. The experiments lasted from seven to ten days each. During this time the total quantity of iron ingested in the form of breast milk and in weaning fluids was determined and quantitative determinations of the iron excreted in the urine and feces were made. In three of the infants the experiments showed a positive iron balance, analogous to that observed by Langstein and Edelstein and which may be considered as the normal balance of children born at term. In one child, also born at term, the iron balance behaved as in the experiments of Lichtenstein on premature infants; that is, it was negative in the first five months but without the production of a decrease in hemoglobin, such as one observes in the anemias of premature infants. In the fifth child, the balance during the first five months was at times negative and at times positive. Although the quantity of iron contained in breast milk averages only 0.642 mg. for 1,000 Gm., it suffices to cover the needs of the infantile organism for iron from the exterior, provided the value of the hemoglobin stays within normal limits. As it may be supposed that this small daily supply of iron is insufficient to cover the total requirements of iron for reconstruction of the blood of the infant and so on, it is probable that the organism is capable of utilizing part of the iron found in its organs at the moment of birth and liberated by the destruction of the erythrocytes. On the other hand, the larger quantities of iron excreted in the feces during the first months may show that a portion of the iron existing in the organs at the moment of birth is eliminated as a waste product, useless to the organism.

Practical Value of New Test of Hepatic Function.—Migneco studied the value of the modification of the dextrose tolerance test of Althausen and his collaborators as an index of metabolic activity of the liver. The test consists of determining the amount of blood sugar after twelve hours of fasting, followed by subcutaneous injection of 20 units of insulin. Twenty minutes later 50 Gm. of dextrose in 500 cc. of water is administered orally, followed by 1 liter of water. The determination of the blood sugar is repeated one-half hour, one hour, two hours and three hours from the ingestion of the dextrose. They observed in normal subjects a glycemic curve with an ascending stage during the first hour (35 per cent increase), followed by a gradual decrease until after three hours the curve had reached its initial stage. Patients with hepatic diseases showed either a hypoglycemic type of curve with an uninterrupted drop of the glycemic rate during the complete test or a hyperhypoglycemic type in which the drop was preceded by an elevated and permanent hyperglycemic phase. They concluded that terminal hypoglycemia, under the conditions of the test, should show a hepatic dysfunction and that the dividing line between normal and pathologic results should be about 70 mg. of dextrose in 100 cc. of serum. The author administered this test to thirty-four patients, of whom nine were normal and thirteen suffered from hepatic diseases, eight from nonhepatic diseases and four from diabetes. He reports on six normal persons and six with diffuse hepatic lesions of various types. Roentgenograms of the six normal persons before the test showed no disturbances, hepatic or otherwise. Yet three of the patients showed hepatic curves while the glycemic rate fell to 67, 46 and 35 mg., respectively. In all cases the glycemia fell to 50 mg. In one, disturbances due to hypoglycemia arose requiring an immediate operation.

The test offered disconcerting results in the six patients with hepatic lesions. The glycemic rate of one dropped to 53 mg., of another to 43 mg. and of a third to 32 mg. Two patients with the most serious hepatic lesions in the group gave negative results, their curves falling to 31 and 22 mg. Since normal persons registered a hepatic type of curve while patients with hepatic diseases showed a normal curve, the author concludes that this test has little merit.

Lipoid Infiltration of Gallbladder.—Berendes submits a histologic study of 127 so-called strawberry gallbladders found among 2,492 necropsies performed in the Pathologic-Anatomic Institute of the University of Freiburg between 1928 and 1932. In a previous work, Ludwig Aschoff stipulated that the small yellowish elevations seen on the gallbladder mucosa were not fat accumulations but an especial form of storing of fat by the endothelial cells of the lymphatic vessels. Chemical analysis showed these to be a mixture of cholesterol ester and fatty acids. They were frequently found in entirely normal gallbladders. The bile in such gallbladders frequently contained small specks which on polaroscopic examination showed the double refraction characteristic of cholesterol crystals and, when reduced to a liquid state, the characteristic maltese cross configuration of cholesterol plaques. By means of the sudan stain the author demonstrated that the lipoid infiltration was limited principally to the endothelial cells of the lymph vessels of the submucous layer. The fact that the richest deposits of cholesterol ester occur in the summit of the projecting mucous villi and that the strawberry gallbladder is frequently associated with bile stasis suggests that the lipoid infiltration here is the result of absorption of cholesterol from the bile rather than of excretion into the bile. A causal relationship is suggested between cholesterol infiltration and cholesterol stone formation. Mucous villi, laden with fat and projecting into a bile saturated with cholesterol, may become detached from their slender pedicles and float as free bodies in the bile. They may serve as nuclei for the formation of gallstones. Addition of desquamated epithelium of the gallbladder to bile in a test tube experiment was shown to augment the precipitation of cholesterol from it. The end product of cholesterol precipitation in stasis of the gallbladder is radial cholesterol stone. Attention is called to the report of Judd and Mentzer in which it is stated that 99 per cent of stones found in instances of strawberry gallbladders seen by them were pure cholesterol stones and that in 30 per cent these were solitary cholesterol stones. In the author's series there were only two instances of mixed stones, while the remaining seven were solitary radial cholesterol stones. The following conclusions were drawn: 1. Storing of lipoids in the wall of the gallbladder is the result of resorption. 2. There is no causal relationship between storing of lipoids and formation of gallstones. 3. Disturbance of the cholesterol metabolism of the entire organism is probably not the cause of lipoid infiltration of the wall of the gallbladder. 4. Storage of lipoids is the result of the process of absorption of increased cholesterol ester content in the gallbladder bile. The slowing of the lymph current appears to have an influence on the process.

Leukocytic Picture in Topical Diagnosis.—On the basis of 15,000 blood counts after the method of Schilling, Hayes and his co-workers draw the following conclusions: 1. The shift to the left does not possess the prognostic value assigned to it by its author. Diseases other than those of the gastrointestinal tract and of the pleura do not display this phenomenon. When the shift to the left does take place in these diseases, it is due to some gastro-intestinal disturbance which can be easily eliminated. 2. The variable size of rods (nuclei) and of juvenile forms is not an accidental but a constant phenomenon and enables one to make a topical diagnosis. 3. The phenomenon of paragglutination is of considerable diagnostic and prognostic significance. It occurs in local as well as in general infections.

Chronic Duodenal Stenosis and Megaduodenum.—Kraas reports seven cases of megaduodenum observed in Schmieden's clinic. He accepts Melchior's and Duval's definition of megaduodenum as an enlargement of the duodenum without recognizable cause, the condition being taken as a congenital anomaly. Another type of chronic duodenal stasis exists; namely, that due to chronic arteriomesenteric obstruction. It may be produced by disorders of the neighboring organs with secondary stenosis of the descending portion of the duodenum or of the duodenojejunal flexure. Enteroptosis, especially of the transverse colon, is considered by some as an important etiologic cause. The symptoms in megaduodenum may be entirely absent. When present, they are characterized by long duration, a sense of fulness in the right upper quadrant of the abdomen and frequently severe, nightly colics in the same region. The clinical picture suggests an ulcer. Roentgen study is the most important method of recognition of the condition, which is frequently associated with a diverticulum or an ulcer. The diverticulum is regarded as a congenital anomaly rather than the result of stenosis. Duodenojejunostomy is considered the operation of choice in the cases in which motor disturbances are prominent. When the presence of an ulcer suggests the advisability of partial gastric resection, a Billroth II operation with the Y anastomosis of Roux is recommended because it is capable of preventing regurgitation of gastric contents into the duodenal stump.

Operative Treatment of Acute Pancreatitis.—Hartlieb is opposed to the prevailing idea of early intervention in acute hemorrhagic pancreatitis. He cites twenty-three cases from the Nordmann clinic in which the operation consisted of the removal of the gallbladder and drainage of the common bile duct. Eleven of the patients got well and twelve died. Two patients were too sick to be operated on. They went on to formation of abscesses which were later drained and they recovered eventually. In a later group of seven patients treated conservatively, five got well and two died. In contradistinction to his own views, the review of recent works by several authors indicates a preference for the earliest possible operative intervention. Unanimity of opinion exists as to the importance of gallstone disease in the etiology of acute pancreatic necrosis. The diagnosis is not particularly difficult. The most valuable test is the serum diastase determination of Wohlgemuth. An increase of the blood sugar is suggestive. Guleke found glycosuria in 10 per cent of his cases. The author quotes instances to show that early operative intervention is not always capable of arresting the destructive process in the pancreas. Effusion into the peritoneal cavity is not as dangerous as was formerly believed, because it is always sterile in the beginning. The introduction of drains, however, converts a sterile process into a suppurating one. All the authors reviewed were in favor of the earliest possible intervention.

Sequelae After Bacillary Dysentery.—Ohly points out that bacillary dysentery is not a uniform disease, etiologically (many different dysentery bacilli) or anatomically (varied and changing symptoms). The same applies also to the late sequelae of the disease. The symptomatology is mainly determined by the localization of the disorder. For the recognition of post-dysenteric disorders, the anamnesis is of great importance. If it reveals that the patient has had sanguineous-mucous diarrhea with tenesmus and fever, he most likely has had a dysenteric disorder. A large percentage of the late sequelae have the aspects of chronic relapsing gastro-enteritis or of gastro-enterocolitis. The colonic symptoms generally predominate. The diarrheal form is mostly painless, but the spastic form is often extremely painful. To insure a correct diagnosis the author recommends careful examination of the feces, roentgenoscopy and endoscopic examination. The differential diagnosis of dysenteric enterocolitis is frequently difficult, because the disorder often simulates such conditions as gastroduodenal ulcer, cholecystopathy, appendicitis and even pancreatic disorders. Moreover, it is possible that one of these disturbances develops on the basis of a chronic dysenteric gastro-enterocolitis. The postdysenteric colitides are frequently complicated by anal eczema. The impairment of the gastro-intestinal mucous membrane is much more severe in the postdysenteric than in other forms of gastro-intestinal disorders, which makes the prognosis comparatively unfavorable. Relapses are frequent, particularly following a carelessness in the diet or an exposure to cold. Food rich in cellulose should not be eaten in large quantities. Fresh yeast bread, food with high fat content and cold drinks are likewise inadvisable. In cases in which carbohydrate fermentation and diarrhea predominate, it is helpful to let the patient fast for a day and to allow him only hot tea. Carbohydrates should be avoided for about a week, during which time the diet should consist primarily of proteins. In patients with achylia, medicinal therapy in the form of hydrochloric acid, pepsin and other preparations is advisable. The application of heat in various forms is also helpful. Because the long duration of the disturbance may lead the patients to develop carcinophobia or other phobias, psychotherapy should not be neglected.

Nonsurgical Treatment of Gonorrheal Ankylosis of Knee Joint.—Mosenthal admits that bony ankylosis requires surgical interventions but shows that fibrous ankylosis, the most frequent form of gonorrheal ankylosis, can be treated nonsurgically. Roentgenoscopy is the best help in determining whether surgical or nonsurgical interventions should be employed, and it is essential to exclude the existence of an infection. To do this the author recommends agglutination tests with the most frequently occurring pathogenic organisms, repeated leukocyte counts, determination of the sedimentation speed of the erythrocytes, mechanical irritation and eventually irritating irradiations. In patients who have had gonorrhea it is essential that the disease be not only completely cured but that there be an interval of at least two years between the cure and the intervention. The author employed nonsurgical mobilization in three cases, in all of which it was successful. In two of the patients the ankylosis had existed for two and three years, respectively. The third patient, whose clinical history is described, had had a stiff knee for seven years. Since the roentgenogram revealed no bony bridges but only proliferations on the articular surfaces, the author decided to

attempt mobilization under deep anesthesia. During an attempt to mobilize the joint, the patella made a cracking noise, and after this it was no longer difficult to attain a 90 degree movement of the knee. The joint was kept in the flexed position for eight days, and after that an intensive movement therapy was begun. The patient is now able to work, is free from pain, and is entirely satisfied with the results. Even a plastic operation would hardly give better results. The author points out that, in two cases of beginning articular complications, he was able to obtain rapid improvement by treatment with roentgen rays (inflammation dose). After a few days, articular movements could be begun and a stiffening of the joints thus prevented.

Hyperproteinemia in Myeloma.—Bönniger relates the history of a man, aged 52, who complained of general debility and of pains in the hips and legs. The patient was extremely pale. The hemoglobin content of the blood was reduced to half the normal value, and the volume of the blood corpuscles was correspondingly decreased. The number of erythrocytes could not be determined because the blood coagulated as soon as it came in contact with Hayem's solution. The blood count could be made in physiologic solution of sodium chloride, and the numbers corresponded to the hemoglobin content (orthochromic anemia). When a drop of blood was put into a 25 per cent solution of corrosive mercuric chloride, coagulation took place immediately, a drop of serum solidifying at once and sinking to the bottom, whereas normal serum forms at first a homogeneous cloudiness and later precipitates. The patient's serum showed still other peculiarities; it was syrupy and was sticky like acacia, and the blood corpuscles, its own as well as foreign ones, had an agglutinative tendency. The sedimentation speed of the erythrocytes was highly accelerated. Bleeding time, coagulation time and fibrinogen content were normal, but the blood clot showed only a slight tendency to retract. It seemed probable that the peculiar behavior of the blood was connected with the protein bodies of the blood plasma. Tests revealed a considerable increase in the specific gravity of the plasma and of the serum, and the refractometer value of the protein was 13 per cent, compared to 8 per cent in normal persons. The nitrogen value was correspondingly increased, and the viscosity could not be measured with the Hess instrument, because the instrument is not standardized for such high protein values. Roentgenoscopy had revealed the typical aspects of myeloma. The changes were most severe in the femurs and the hip bones. The author points out that other reports on myeloma mention changes in the blood status, such as an increase in the euglobulin, but that only two state that it was impossible to count the erythrocytes. However, these authors do not mention whether they employed Hayem's solution. At any rate, it is noteworthy that the coagulation set in only during the erythrocyte count, whereas other tests, such as the determination of the hemoglobin and the white blood count, could be made. Another worker mentions coagulation at the withdrawal of blood for the Wassermann test, whereas other blood tests apparently could be made without difficulty. The author concludes that the blood condition in myeloma probably varies in different cases, but he thinks that, if the described phenomenon is observed, the possibility of a myeloma should be considered.

Abscesses of Cerebellum.—The anamnesis of Stern's first patient reveals that fifteen years previously he had an osteomyelitis of the right arm, surgically treated by removal of the

head of the humerus. The patient also stated that for many years he had been hard of hearing in the right ear. Following the first operation, he suffered from severe headaches, recurring every summer and radiating toward the occiput, where they produced a feeling of pressure. In the past they lasted two weeks, but because this year they lasted longer and recurred after an interval of one month, the patient asked for medical advice. The patient's condition grew rapidly worse and he died about two weeks later, twelve hours after a spinal puncture. The necropsy revealed, in the right cerebropontile angle, suppurative meningitic deposits, which also covered parts of the right cerebellar hemisphere. The cerebellum was swollen and was pressed tightly into the large occipital foramen. In the lateral portion of the cerebellum there was an abscess cavity the size of a cherry and filled with pus. The author discusses the symptomatology of cerebellar abscesses and the peculiar aspects of this case. Whether the cerebellar abscess originated in the osteomyelitis cannot be definitely decided. There is also the possibility that the two conditions had a common origin. The hypertrophic pharyngeal ring and the bad condition of the tonsils make it appear possible. At any rate, the case shows that a long time may pass between the primary infection and the manifestation of a cerebellar abscess. The second case described is that of a man with a psychopathic predisposition. Six months before his death he showed psychic changes and complained of headaches in the occipital region. An examination made two months before the fatal outcome revealed no organic symptoms, except a nystagmus toward the right side. The author emphasizes the significance of nystagmus as a sign of cerebellar abscess. The symptoms in this patient also became considerably exacerbated following a spinal puncture, and he died a few days later. The postmortem examination revealed a cerebellar abscess. The author thinks that the sudden death of both patients was the result of spinal puncture, for in both patients the cerebellum was swollen and was pressed into the occipital foramen. Under these conditions, a sudden movement may easily cause an impairment of the oblongata and result in respiratory paralysis. Consequently the author warns against spinal puncture whenever there is a possibility of cerebellar abscess.

Complication of Suppurative Mastoiditis.—Lorenzo and Delatienda reject the theory that mastoiditis is always a secondary localization of a process in the middle ear. The case reported by them showed from the beginning primary symptoms at the focus of the disease. On the basis of their clinical and anatomic observations they conclude that the disorder was a primary osteomyelitic mastoiditis with manifestations corresponding to Bezold's mastoiditis. The suppuration spread into the deeper layers of the neck and into the lateral portions of the pharynx. The osteomyelitis involved the left occipital condyle and the epistropheus and the atlas, and the intravertebral ligaments were also destroyed. An incomplete Brown-Séquard syndrome developed as the result of extradural compression of the first cervical segment. Death was caused by compression of the medulla oblongata resulting from the dislocation of the occiput and of the atlas against the epistropheus. The authors base their contention that the process was primary on the following factors: lack of a preceding disturbance of the middle ear, sudden beginning of the osteomyelitic processes, normal condition of the middle ear and a special affinity of the pathogenic organisms for bony tissue, which was exemplified by the osteomyelitic processes in the cervical spinal cord.

Reduction of Sedimentation Rate in Neurotic Persons.

—In 157 patients with functional neuroses or with psychopathy, Range observed a retardation of the sedimentation speed of the erythrocytes from 1 to 3.5 mm. per hour. Women and men were represented in this material in the ratio of 1:2. From the study of twenty-two patients the author gained the impression that the sedimentation speed of erythrocytes is largely dependent on the fibrinogen and on the changes in the plasma protein. Low sedimentation speed of the erythrocytes was always accompanied by abnormally low fibrinogen values, whereas control tests on sixteen persons with increased sedimentation speed of the erythrocytes revealed high fibrinogen values. The tests seem to indicate also that there is a relationship between sedimentation speed and increase in the globulin content. Low globulin values always were accompanied by retardation of the sedimentation, and this decrease of the globulin was always present in neurotic patients with decreased sedimentation speed.

Splenectomy in Gaucher's Disease.—Ullrich shows that in patients with Gaucher's disease (familial splenic anemia) splenectomy has its advantages and its disadvantages. He reports a case in which splenectomy averted the acute danger to the child from severe anemia and hemorrhagic diathesis and improved the general condition. But soon after the operation, skeletal changes of a progressive, destructive character became manifest. Although roentgenoscopy before the splenectomy did not show involvement of the skeletal system, it is possible that the bone marrow was already involved and, if a disturbance in the lipid metabolism is the principal factor in Gaucher's disease, it becomes understandable that following extirpation of the main organ of storage, the spleen, the bone processes should become more progressive. The author concludes that since splenectomy does not influence the metabolic disturbance, which is the underlying cause of the disease, the diagnosis Gaucher's disease does not justify the intervention. The danger of diverting the storage into the skeletal system militates against splenectomy, unless the patient's life is in acute danger from severe anemia or hemorrhagic diathesis, or a huge splenic tumor makes life extremely difficult. Only in such cases will the prospects of a successful operation counterbalance the risk of osseous manifestations.

Combination Therapy of Anemia.—It is demonstrated by Hantschmann that in the university children's clinic in Königsberg the treatment of anemic children has been more successful in the last three years than was the case in the preceding years. He ascribes this to the use of a combination therapy. The milder cases were treated with iron and liver, and in severe cases blood transfusions were added. This combination therapy hastened recovery and improved the final results of the treatment. The author thinks that iron is best in the form of reduced iron and that liver should be given in the form of powder or extract. Hemotherapy is most advantageous in intravascular administration. Case reports show that the combination therapy was successfully employed in children with alimentary anemia, postinfectious anemia, Jacksch-Hayem's anemia, secondary anemia, and anemia of premature infants and of children with rickets. The author resorted to the combination therapy also in other disorders of the hematopoietic system. In lymphatic leukemia, aleukemia and myeloid leukemia, the combined application of iron, liver and blood transfusion failed, in that the improvement was only of short duration, but in a child with lymphogranulomatosis the combined application of iron and liver increased the hemoglobin content and the number of the erythrocytes, so that radiation therapy could be commenced. Of two cases of hemorrhagic purpura, one yielded to repeated blood transfusions and the other one to combined iron and liver therapy.

Diarrhea in Nurslings.—According to Langer and Pipirs, food remains in the stomach, to be separated into its constituents. The defective separation of a milk food is the essential factor in the pathogenesis of diarrhea in nurslings, for it supplies the small intestine with a chyme that furthers the growth of a pathologic flora. If the defective separation is combined with a prolongation of the retention of the food in the stomach, which is the case in a food with a high fat content, stagnation of the entire gastric contents is the result, and this

prepares the way for bacterial disintegration in the stomach. Promotion of the separation of the gastric contents should therefore be the aim of the antidyspeptic diets. The separation of the gastric content is promoted by the addition of sugar to the milk, whereas the addition of fat retards the separation and with it the evacuation of the stomach.

Peroxidase Reaction of Myeloid Leukocytes.—Mascher calls attention to Sato's method of peroxidase demonstration in the leukocytes and to the phenomenon discovered by means of it; namely, a disappearance of the peroxidases of the leukocytes in neurologic disorders. Because Sato first thought processes in the corpus striatum responsible for this phenomenon, he referred to it as the "striatal blood syndrome." The author found that Sato's peroxidase reaction is superior to the formerly employed methods. The technic is simple and it is helpful in differentiating myelogenic and nonmyelogenic cells. The large monocytes always prove to be peroxidase positive in this reaction. Staining with low concentrations of hydrogen dioxide and observation of the pathologic blood pictures make it appear probable that the peroxidase content of the different granules in the cells is not the same. Since a certain minimum of ferment is necessary to produce the reaction, staining with low concentrations of hydrogen dioxide is frequently not sufficient to demonstrate the granules. The same behavior is observable in the pathologic reduction of the peroxidases in the leukocytes. In both instances, the result is a more or less pronounced reduction in the number of granules. Only this reduction in number is pathologic, and a fluctuation in the intensity of staining of the demonstrated granules has no demonstrable pathologic significance. The reduction of the peroxidases in the leukocytes which is dependent on the pathologic granulation is to be differentiated from the manifestations resembling the striatal blood syndrome. The author thinks that Sato's theory, that the striatal syndrome is caused by a focal lesion on the floor of the third ventricle, is not definitely established, for in tests on forty patients with chronic encephalitis, the typical striatal blood syndrome was not observed. In one patient there was a noticeable reduction in the peroxidase content of the myeloid leukocytes, and this could perhaps be considered as a phenomenon resembling the striatal blood syndrome.

Chyluria.—It is pointed out by Lucke that the etiology of tropical, parasitic chyluria is understood, because, owing to the anatomic impairment of the lymphatic system by the parasites, there develops a direct communication between the lymph vessels and the urinary tract. In nonparasitic chyluria, however, the pathogenesis is not so clearly understood. In the reported case the chylous urine was secreted bilaterally. The specific gravity of the urine indicated that not all constituents of the lymph were present in the urine, and it seems likely that the transfer took place in the kidney, as the unchanged lymph should have appeared in the urine in case of a direct communication between lymph channels and descending urinary passages. The author points out that the kidney itself contains lymph vessels and that the glomeruli contain lymph capillaries. However, it is unlikely that some constituents of the urine find their way directly from them to the descending urinary passages. It

appears more probable that the glomeruli pass the unchanged lymph and that certain constituents are reabsorbed in the tubules. A connection between a disturbance in the region of the glomeruli and the chyluria seems the more probable, since a functional disturbance of the kidney concurred with the chyluria and subsided simultaneously with it. By means of a fat-free diet the chyluria could be reduced to a minimum. The author does not wish to base etiologic generalizations on the study of one case, and he is inclined to believe that chyluria may be produced by various causes.

Distant Complications in Gonorrhea.—Damblié reports one case of gonorrheal sepsis with severe ulcerous endocarditis, swelling of the liver and spleen and acute diffuse glomerular nephritis. It was not possible to obtain cultures of gonococci fourteen hours after death, but they were demonstrable in the histologic preparation of the aortic valves. The second case history concerns a patient who developed meningitis following a gonorrheal reinfection. The urethral secretion contained numerous gonococci and there was a gonorrheal epididymitis on the left side. Lumbar puncture revealed a considerable increase in pressure, a marked increase in the number of cells, positive protein reactions and a negative Wassermann reaction. In spite of several examinations it was not possible to demonstrate the gonococcus or any other form of coccus in the cerebrospinal fluid. All cultures remained sterile. Antigonorrheal treatment and two spinal punctures led to recovery.

Hemorrhagic Diatheses and Carcinoma.—Beiglbock gives the histories of two patients who presented the clinical aspects of hemorrhagic diathesis, and in whom the necropsy revealed a carcinoma. The reported cases have in common the advanced age of the patients and arteriosclerotic changes, but there are also factors in which they differ. In the first patient the vessels were impaired by the carcinoma and by inflammatory processes (appendicitis, pneumonia), and this may have led to the cutaneous hemorrhages, without severe changes in the blood. In the second case, however, changes in the blood, which in turn must be traced to extensive carcinomatous metastasization in the bone marrow, were the essential factor in the pathogenesis of the hemorrhagic diathesis. The thrombopenia, detected at the first examination, increased rapidly. The author found that reports of carcinoma without metastases of the bone marrow and with hemorrhagic diathesis are rare, but that the concurrence of metastases of the bone marrow with thrombopenia and with hemorrhagic diathesis has been reported more often. He considers it advisable to search for a carcinoma whenever older patients have a hemorrhagic diathesis of unknown origin.

Prevention of Gas Gangrene.—Among 20,000 open traumatic wounds treated by Böhler in the past seven years, there were 253 compound fractures of the long bones and more than 100 open tears of the large joints. Only one patient in this group died of gas gangrene, though gas gangrene serum was regularly omitted in the treatment. The one fatal outcome was in a patient with tearing and soiling of the calf muscles. The popliteal artery did not pulsate. In his experience, absence of the popliteal pulse in the presence of an extensive injury to the soft parts always resulted in moist gangrene. It is obvious that the use of prophylactic serum in these cases is of no avail, since the part deprived of circulation must die. The author was frequently able to demonstrate the presence of gas gangrene bacteria in wounds by the culture method without, however, the subsequent development of clinical symptoms of gangrene. Gangrene develops principally as the result of interference with the blood supply of a part. An immediate amputation of the lower extremity is indicated when, following an extensive injury to soft parts, the peripheral pulse cannot be palpated and the toes are pale and cold. When the blood supply is adequate, a careful excision of the traumatized tissues is indicated. Since this operation occupies from one to three hours, general anes-

thesia is never resorted to. After the excision, the leg is immobilized in a fenestrated plaster cast. The author considers the use of strong antiseptics injurious to the tissues and likewise objects to leaving foreign bodies in the wound. Only the most necessary ligations of arteries are performed and suture of bones or of soft parts is omitted. The author concludes that his experience in treating 20,000 patients with open traumatic wounds without the gas gangrene serum indicates the importance of the surgical rather than the serologic prophylaxis.

Benign Tumors of Stomach.—From a study of eighteen cases of benign tumor of the stomach, Reinberg and Rotermel make the following deductions: 1. Roentgen studies make it possible to diagnose benign gastric tumors. 2. The clinical course of these tumors is variable. 3. Acute hemorrhages leading to high grade secondary anemia or simulating pernicious anemia are rather frequent manifestations. Every patient suffering from an anemia of unknown cause should be submitted to a roentgenologic study of the gastro-intestinal tract. 4. Benign tumors situated in the pyloric portion may cause an acute obstruction or a chronic intermittent obstruction. Pedunculated tumors not infrequently prolapse into the duodenum. 5. These tumors must be regarded as precancerous conditions, since their malignant transformation is quite common. 6. The authors recommend surgical removal of the tumors even though they cause no symptoms. They point out that roentgenologically diagnosed benign tumors of the stomach may not be palpable at the time of operation through the wall of the stomach and may therefore be overlooked unless inspection of the interior is undertaken through a gastrostomy incision.

*Barbitism, New Narcomania. G. Rylander.—p. 647.

Allergic Complications in Treatment of Diabetes with Insulin. E. Jorpes.—p. 654.

Barbitism.—Rylander reviews the literature and states that poisoning due to the intake of barbituric acid derivatives as soporific substances has become prevalent in Sweden in recent years. The author adds, however, that many cases were falsely diagnosed in the past and that the treatment of addiction to drugs in general concerns a psychiatrist or neurologist more than an internist. Barbitism is often mistaken for dementia paralytica; many patients taking small amounts of the derivatives daily for a long period of time are gradually poisoned and develop these paralytic symptoms. Some authors speak of a pseudo-encephalitic type and a pseudocerebral type of barbitism. Several French authors found that small doses of barbital administered gradually in animals cause excitation, motor disturbances and spasms. The smallest lethal dose of barbital is 0.65 Gm.; the average fatal dose, 3.25 Gm. Addicts are in the majority persons with psychopathic tendencies. The characteristic symptoms of barbitism are stupor, coma, amnesia, incoordination, inability to concentrate, impaired speech and general lethargy. In more serious cases, some of the symptoms are deep coma, cyanosis, facial paralysis, incontinence of urine and feces, and low blood pressure. Diagnosis, which is often difficult, is sometimes made by the discovery of barbituric acid derivatives in the urine or stomach contents. The author presents six cases of gradual poisoning due to the constant intake of barbital, bromural and phenobarbital. The majority of the patients were high strung and emotional and improved with psychiatric treatment. The author concludes that barbitism is a true toxicomania.

IMPORTANCE OF CLINICAL-PATHOLOGIC CONFERENCES IN WORK OF THE PRACTITIONER AS TEACHER

CHAIRMAN'S ADDRESS

REGINALD FITZ, M.D.
BOSTON

The Council on Medical Education and Hospitals has assembled some striking figures in its most recent report.¹ In 1932, there were 6,562 registered hospitals in the United States with a total capacity of more than 1,000,000 beds; the number of patients admitted to these hospitals during the year was 7,228,151. To carry on such a huge hospital practice, 7,757 interns and 2,018 resident physicians were employed. These 10,000 apprentices worked under the guidance of a teaching staff of 101,518 older and more experienced visiting men. On the shoulders of this visiting staff, therefore, falls the responsibility for carrying on the most important concerted effort at systematic postgraduate instruction that is being conducted in this country at the present moment.

Since more than 100,000 of the 125,000 practicing physicians in this country are directly associated or affiliated with hospitals, it follows that the vast majority of physicians who attend the annual meeting of the American Medical Association must occupy responsible hospital positions, have working under them varying numbers of interns and residents, and, therefore, are to be considered as actively engaged in the teaching of medicine. I have an impression that many practitioners are not wholly alive to their responsibilities as teachers and do not carry on such teaching of medicine as they are expected to perform, as enthusiastically and vigorously as is desirable.

The importance of clinical-pathologic correlation as a means of teaching medicine has been recognized for many years. Yet in a group of 664 hospitals which the Council investigated in 1931, from this point of view, only 86 of them (13 per cent) performed necropsies in more than one half of their fatal cases. These figures suggest that there still exists a good deal of inertia toward such an important method of instruction on the part of the hospital teaching staff. It is on the educational value of the clinical-pathologic conference that I shall dwell here.

PERMISSION TO PERFORM NECROPSIES
